Chapter 1
Introduction

ETABS automates several slab and mat design tasks. Specifically, it integrates slab design moments across design strips and designs the required reinforcement; it checks slab punching shear around column supports and concentrated loads; and it designs shear link and shear stud if needed. The actual design algorithms vary based on the specific design code chosen by the user. This manual describes the algorithms used for the various codes.

It should be noted that the design of reinforced concrete slabs is a complex subject and the design codes cover many aspects of this process. ETABS is a tool to help the user in this process. Only the aspects of design documented in this manual are automated by ETABS design capabilities. The user must check the results produced and address other aspects not covered by ETABS.

1.1 Slab Design

ETABS slab design procedure involves defining sets of strips in two mutually perpendicular directions. The locations of the strips are usually governed by the locations of the slab supports. The axial force, moments and shears for a particular strip are recovered from the analysis (on the basis of the Wood-Armer technique), and a flexural design is carried out based on the ultimate strength design method. As an alternative to this strip based method, ETABS also offers a FEM
Welcome to ETABS

based design, which is useful for irregular slabs where strip based techniques may not be appropriate.

1.2 Design Strips

ETABS provides two principal strip layers used for design, namely Layer A design strips and Layer B design strips. The strips are defined as polylines with associated widths that can vary along the length of the strip.

The strips need not be mutually perpendicular. The extent of the design strips is defined by the edges of the area objects defining the slab, and strips can overlap if needed. The location of the design strips is usually governed by the support or grid locations. Design strips may be defined as either Column Strips or Middle Strips – models with post-tensioning typically have column strips only.

1.3 Integration of Moments – Wood-Armer

Use of the Wood-Armer method for the integration of design moments results in the following steps:

For a particular combination or load case, for each finite element within the design strip, ETABS calculates the design moments per unit width using the internal forces. Internal forces are converted to design moments per unit width in the following manner:

\[
\begin{align*}
    m_{bB} &= m_B + |m_{AB}| \\
    m_{bA} &= m_A + |m_{AB}| \\
    m_{tB} &= m_B + |m_{AB}| \\
    m_{tB} &= m_A + |m_{AB}|
\end{align*}
\]

where \( m_A, m_B, \) and \( m_{AB} \) are internal moments per unit width, and \( m_{bA} \) and \( m_{bB} \) are design moments per unit width for the bottom of the slab in the A and B directions, respectively, and \( m_{tA} \) and \( m_{tB} \) are the design moments for the top of the slab in the A and B directions, respectively. Design moments may be factored combinations for strength design, or unfactored moments for service load checks.
when post-tensioning is present. The design moments calculated using the Wood-Armer integration will most likely not completely satisfy equilibrium of the applied loads, but for a mesh that accurately captures the overall behavior of the slab, this integration scheme provides a good design. This is the case because the Wood-Arner integration scheme effectively calculates design moments when cracking occurs diagonally to the design strip directions.

1.4 Required Reinforcement – Strip Based

The design of the mild reinforcement for slabs is carried out for a particular strip at each transverse mesh line location along the length of the strip. The moments are integrated across all elements of like property in the strip to determine the factored design moments. The required reinforcement for slabs is computed for each set of elements with the same property type, and then summed to give the total required reinforcement for the strip. The maximum required top and bottom strip reinforcement for a particular mesh line is obtained, along with the corresponding controlling combinations.

As an option, minimum reinforcement requirements may be enforced in accordance with the selected design code.

1.5 Required Reinforcement – FEM Based

The FEM Based design determines the required reinforcement on an element-by-element basis and is therefore independent of design strips. Several options are available for refining the display of the required reinforcement, including averaging, which will flatten peaks and provide an averaged required reinforcement over a particular area of the slab.

1.6 Slab Punching Shear Check

The distribution of stresses close to concentrated loads or reaction points in reinforced and prestressed concrete slabs is quite complex. Punching shear is one particular failure mode recognized by design codes for which an elastic plate bending analysis may not provide adequate stress distribution. Most codes use empirical methods based on experimental verification to check against punching shear failures. ETABS automates this check for common geometries. If the
check results in a punching shear ratio greater than unity (i.e., punching failure), ETABS will design punching shear reinforcement. The ETABS procedure for the punching shear check carried out for each column, for each design combination is as follows:

Locate the critical section around the column or point load. ETABS reports whether it assumed the column to be an interior, edge, or corner column. This determination is based on whether the slab is present within 10 times the slab thickness along the column edges. A column is classified as a corner column when two slab edges are found within 10 times the slab thickness. A column with only one slab edge within 10 times the slab thickness is classified as an edge column, and a column is classified as interior when no slab edges are found within 10 times the slab thickness. For single footings, this determination is based on the minimum area of the critical section.

Check that each slab element in the area enclosed between the face of the column and the critical section for punching shear has the same slab property label. If this is not the case, the minimum slab thickness within the punching shear perimeter is used.

Use the net shear to check punching shear if a point load or column (call it load/column A) is within the critical section for punching shear for another point load or column (call it load/column B).

Calculate punching shear based on net forces in the slab when line objects (beams, walls, or releases) frame into a column.

Calculate the reactive force and moments at the column for the combination. The shear and moment values used in the punching shear check are reduced by the load (or reaction) that is included within the boundaries of the punching shear critical section.

Calculate the distribution of shear stress around the critical section.

Obtain the shear capacity of the critical section.

Compare the shear stress distribution with the shear capacity. The comparison is reported as a ratio for the worst combination. A value above 1.0 indicates failure.
ETABS designs rebar ties or stud rails when such options are activated in the punching shear design overwrites. The details of rebar ties or stud rails are documented in the *Reinforced Concrete Design Manual* and the *Post-Tensioned Concrete Design Manual*.

Design overwrites are available to modify the location type, punching shear perimeter, openings in the slab, and reinforcement pattern, when the punching shear parameters computed need to be changed.

For computing the punching parameters, the following assumptions are used:

Punching shear is calculated for columns punching through a slab or a drop panel. ETABS also checks the drop panel punching through a slab. The effect of column capitals is included in the punching shear calculation.

ETABS uses the effective depth for computing the punching shear. The concrete cover to rebar is taken from the design preferences unless a design strip is present. In that case, the rebar cover is taken from the design strip.

Openings within 10 times the slab thickness are automatically included in the punching shear calculations. The slab edge within the punching zone radius is subtracted from the punching shear perimeter.
This chapter describes in detail the various aspects of the concrete slab design procedure that is used by ETABS when the American code ACI 318-14 [ACI 2014] is selected. Various notations used in this chapter are listed in Table 2-1. For referencing to the pertinent sections or equations of the ACI code in this chapter, a prefix “ACI” followed by the section or equation number is used herein.

The design is based on user-specified load combinations. The program provides a set of default load combinations that should satisfy the requirements for the design of most building type structures.

English as well as SI and MKS metric units can be used for input. The code is based on inch-pound-second units. For simplicity, all equations and descriptions presented in this chapter correspond to inch-pound-second units unless otherwise noted.

2.2 Design Load Combinations

The design load combinations are the various combinations of the load cases for which the structure needs to be designed. For ACI 318-14, if a structure is subjected to dead (D), live (L), pattern live (PL), snow (S), wind (W), and earthquake (E) loads, and considering that wind and earthquake forces are reversible, the following load combinations may need to be considered (ACI 5.3.1):

1.4D  
1.2D + 1.6L + 0.5$L_r$  
1.2D + 1.0L + 1.6$L_r$  
1.2D + 1.6(0.75 PL) + 0.5$L_r$  
1.2D + 1.6L + 0.5S  
1.2D + 1.0L + 1.6S  
0.9D ± 1.0W  
1.2D + 1.0L + 0.5$L_r$ ± 1.0W  
1.2D + 1.6$L_r$ ± 0.5W  
1.2D + 1.6S ± 0.5W  
1.2D + 1.0L + 0.5S ± 1.0W

2 - 4 Design Load Combinations
These are the default design load combinations in ETABS whenever the ACI 318-14 code is used. The user should use other appropriate load combinations if roof live load is treated separately, or if other types of loads are present.

2.3 Limits on Material Strength

The concrete compressive strength, \( f'_{c} \), should not be less than 2,500 psi (ACI 19.2.1, Table 19.2.1.1). The upper limit of the reinforcement yield strength, \( f_{y} \), is taken as 80 ksi (ACI 20.2.2.4a, Table 20.2.2.4a) and the upper limit of the reinforcement shear strength, \( f_{y't} \), is taken as 60 ksi (ACI 21.2.2.4a, Table 21.2.2.4a).

If the input \( f'_{c} \) is less than 2,500 psi, ETABS continues to design the members based on the input \( f'_{c} \) and does not warn the user about the violation of the code. The user is responsible for ensuring that the minimum strength is satisfied.

2.4 Strength Reduction Factors

The strength reduction factors, \( \phi \), are applied to the specified strength to obtain the design strength provided by a member. The \( \phi \) factors for flexure, shear, and torsion are as follows:

\[
\phi = 0.90 \text{ for flexure (tension controlled)} \quad (\text{ACI 21.2.1, Table 21.2.1})
\]
\[
\phi = 0.75 \text{ for shear and torsion} \quad (\text{ACI 21.2.1, Table 21.2.1})
\]

These values can be overwritten; however, caution is advised.

2.5 Slab Design

ETABS slab design procedure involves defining sets of strips in two mutually perpendicular directions. The locations of the strips are usually governed by the locations of the slab supports. The axial force, moments and shears for a partic-
ular strip are recovered from the analysis (on the basis of the Wood-Armer technique), and a flexural design is carried out based on the ultimate strength design method.

The slab design procedure involves the following steps:

- Design flexural reinforcement
- Design shear reinforcement
- Punching check

2.5.1 Design Flexural Reinforcement

For slabs, ETABS uses either design strips or the finite element based design to calculate the slab flexural reinforcement in accordance with the selected design code. For simplicity, only strip-by-strip design is documented in the proceeding sections.

The design of the slab reinforcement for a particular strip is carried out at specific locations along the length of the strip. These locations correspond to the element boundaries. Controlling reinforcement is computed on either side of those element boundaries. The slab flexural design procedure for each load combination involves the following:

- Determine factored axial loads and moments for each slab strip.
- Design flexural reinforcement for the strip.

These two steps, described in the text that follows, are repeated for every load combination. The maximum reinforcement calculated for the top and bottom of the slab within each design strip, along with the corresponding controlling load combination, is obtained and reported.

2.5.1.1 Determine Factored Moments

In the design of flexural reinforcement of concrete slab, the factored moments for each load combination at a particular design strip are obtained by factoring the corresponding moments for different load cases, with the corresponding load factors.
The slab is then designed for the maximum positive and maximum negative factored moments obtained from all of the load combinations. Calculation of bottom reinforcement is based on positive design strip moments. In such cases, the slab may be designed as a rectangular or flanged slab section. Calculation of top reinforcement is based on negative design strip moments. In such cases, the slab may be designed as a rectangular or inverted flanged slab section.

2.5.1.2 Determine Required Flexural Reinforcement

In the flexural reinforcement design process, the program calculates both the tension and compression reinforcement. Compression reinforcement is added when the applied design moment exceeds the maximum moment capacity of a singly reinforced section. The user has the option of avoiding compression reinforcement by increasing the effective depth, the width, or the strength of the concrete. Note that the flexural reinforcement strength, $f_y$, is limited to 80 ksi (ACI 20.2.2.4a), even if the material property is defined using a higher value.

The design procedure is based on the simplified rectangular stress block, as shown in Figure 2-1 (ACI 22.2.2). Furthermore, it is assumed that the net tensile strain in the reinforcement shall not be less than 0.005 (tension controlled) (ACI 21.2.2, Table 21.2.2) when the concrete in compression reaches its assumed strain limit of 0.003. When the applied moment exceeds the moment capacity at this design condition, the area of compression reinforcement is calculated assuming that the additional moment will be carried by compression reinforcement and additional tension reinforcement.

The design procedure used by ETABS, for both rectangular and flanged sections (L- and T-shaped sections), is summarized in the text that follows. For reinforced concrete design where design ultimate axial compression load does not exceed $0.1f'_cA_g$ (ACI 9.5.2.1), axial force is ignored; hence, all slab are designed for major direction flexure, shear, and punching check only. Axial compression greater than $0.1f'_cA_g$ and axial tensions are always included in flexural and shear design.
2.5.1.2.1 Design of uniform thickness slab

In designing for a factored negative or positive moment, \( M_u \) (i.e., designing top or bottom reinforcement), the depth of the compression block is given by \( a \) (see Figure 2-1), where,

\[
a = d - \sqrt{d^2 - \frac{2|M_u|}{0.85 f_c' \phi b}}
\]  

(ACI 22.2.2)

and the value of \( \phi \) is taken as that for a tension-controlled section, which by default is 0.90 (ACI 9.3.2.1) in the preceding and the following equations.

The maximum depth of the compression zone, \( c_{max} \), is calculated based on the limitation that the tension reinforcement strain shall not be less than \( \varepsilon_{min} \), which is equal to 0.005 for tension controlled behavior (ACI 21.2.2, Table 21.2.2):

\[
c_{max} = \frac{\varepsilon_{cmax}}{\varepsilon_{cmax} + \varepsilon_{min}} d
\]  

(ACI 22.2.1.2)
where,
\[ \varepsilon_{\text{cmax}} = 0.003 \quad \text{(ACI 21.2.2, Fig R21.2)} \]
\[ \varepsilon_{\text{emin}} = 0.005 \quad \text{(ACI 21.2.2, Fig R21.2.26)} \]

The maximum allowable depth of the rectangular compression block, \( a_{\text{max}} \), is given by:
\[ a_{\text{max}} = \beta_1 \varepsilon_{\text{cmax}} \quad \text{(ACI 22.2.2.4.1)} \]
where \( \beta_1 \) is calculated as:
\[ \beta_1 = 0.85 - 0.05 \left( f' \frac{c_0 - 4000}{1000} \right), \quad 0.65 \leq \beta_1 \leq 0.85 \quad \text{(ACI 22.2.2.4.3)} \]

- If \( a \leq a_{\text{max}} \) (ACI 10.3.4), the area of tension reinforcement is then given by:
\[ A_y = \frac{M_u}{\phi f_y \left( d - \frac{a}{2} \right)} \]
This reinforcement is to be placed at the bottom if \( M_u \) is positive, or at the top if \( M_u \) is negative.

- If \( a > a_{\text{max}} \), compression reinforcement is required (ACI 9.3.3.1, 21.2.2, Fig 21.2.26, 22.2.2.4.1) and is calculated as follows:
  - The compressive force developed in the concrete alone is given by:
\[ C = 0.85 f' \cdot ba_{\text{max}} \quad \text{(ACI 22.2.2.4.1)} \]
and the moment resisted by concrete compression and tension reinforcement is:
\[ M_{uc} = \phi C \left( d - \frac{a_{\text{max}}}{2} \right) \]
- Therefore the moment required to be resisted by compression reinforcement and tension reinforcement is:
ETABS Reinforced Concrete Slab Design

\[ M_{us} = M_u - M_{uc} \]

- The required compression reinforcement is given by:

\[ A'_s = \frac{M_{us}}{\phi(f'_s - 0.85f'_c)(d - d')} \], where

\[ f'_s = E_s \varepsilon_{c,\text{max}} \left( \frac{c_{\text{max}}}{c_{\text{max}}} - d' \right) \leq f_y \] (ACI 9.2.1.2, 9.5.2.1, 20.2.2, 22.2.1.2)

- The required tension reinforcement for balancing the compression in the concrete is:

\[ A_{s1} = \frac{M_{uc}}{\phi f_y \left( d - \frac{a_{\text{max}}}{2} \right)} \]

and the tension reinforcement for balancing the compression reinforcement is given by:

\[ A_{s2} = \frac{M_{us}}{\phi f_y (d - d')} \]

Therefore, the total tension reinforcement is \( A_s = A_{s1} + A_{s2} \), and the total compression reinforcement is \( A'_s \). \( A_s \) is to be placed at the bottom and \( A'_s \) is to be placed at the top if \( M_u \) is positive, and vice versa if \( M_u \) is negative.

2.5.1.2.2 Design of nonuniform thickness slab

In designing a nonuniform thickness slab, a simplified stress block, as shown in Figure 2-2, is assumed if the flange is under compression, i.e., if the moment is positive. If the moment is negative, the flange comes under tension, and the flange is ignored. In that case, a simplified stress block similar to that shown in Figure 2-1 is assumed on the compression side.
2.5.1.2.2.1 Flanged Slab Section Under Negative Moment

In designing for a factored negative moment, $M_u$ (i.e., designing top reinforcement), the calculation of the reinforcement area is exactly the same as described previously, i.e., no flanged data is used.

2.5.1.2.2.2 Flanged Slab Section Under Positive Moment

If $M_u > 0$, the depth of the compression block is given by:

$$a = d - \sqrt{d^2 - \frac{2M_u}{0.85 f'_c \phi b_f}} \quad \text{(ACI 22.2)}$$

where, the value of $\phi$ is taken as that for a tension-controlled section, which by default is 0.90 (ACI 21.2.1, 21.2.2, Table 21.2.1, Table 21.2.2) in the preceding and the following equations.

The maximum depth of the compression zone, $c_{\text{max}}$, is calculated based on the limitation that the tension reinforcement strain shall not be less than $\varepsilon_{\text{min}}$, which is equal to 0.005 for tension controlled behavior (ACI 9.3.3.1, 21.2.2, Fig 21.2.26):
\[ c_{\text{max}} = \frac{\varepsilon_{c,\text{max}}}{\varepsilon_{c,\text{max}} + \varepsilon_{s,\text{min}}} d \]  

where,
\[ \varepsilon_{c,\text{max}} = 0.003 \]  
\[ \varepsilon_{s,\text{min}} = 0.005 \]

The maximum allowable depth of the rectangular compression block, \(a_{\text{max}}\), is given by:
\[ a_{\text{max}} = \beta_1 c_{\text{max}} \]  

where \(\beta_1\) is calculated as:
\[ \beta_1 = 0.85 - 0.05 \left( \frac{f'_c - 4000}{1000} \right), \quad 0.65 \leq \beta_1 \leq 0.85 \]

- If \(a \leq h_f\), the subsequent calculations for \(A_s\) are exactly the same as previously defined for the rectangular uniform slab design. However, in this case, the width of the slab is taken as \(b_f\). Compression reinforcement is required if \(a > a_{\text{max}}\).
- If \(a > h_f\), the calculation for \(A_s\) has two parts. The first part is for balancing the compressive force from the flange, \(C_f\), and the second part is for balancing the compressive force from the web, \(C_w\), as shown in Figure 2-2. \(C_f\) is given by:
\[ C_f = 0.85 f'_c \left( b_f - b_w \right) \text{min}(h_f, a_{\text{max}}) \]

Therefore, \(A_{s1} = \frac{C_f}{f_y}\) and the portion of \(M_u\) that is resisted by the flange is given by:
\[ M_{u1} = \phi C_f \left( d - \frac{\text{min}(h_f, a_{\text{max}})}{2} \right) \]

Again, the value for \(\phi\) is 0.90 by default. Therefore, the balance of the moment, \(M_u\), to be carried by the web is:
\( M_{uw} = M_u - M_{sf} \)

The web is a rectangular section with dimensions \( b_w \) and \( d \), for which the design depth of the compression block is recalculated as:

\[
a_1 = d - \sqrt{d^2 - \frac{2M_{uw}}{0.85 f'_c \phi b_w}} \tag{ACI 22.2}
\]

• If \( a_1 \leq a_{max} \) (ACI 9.3.3.1, 21.2.2), the area of tension reinforcement is then given by:

\[
A_{s2} = -\frac{M_{uw}}{\phi f_y \left(d - \frac{a_1}{2}\right)}, \text{ and}
\]

\[
A_s = A_{s1} + A_{s2}
\]

This reinforcement is to be placed at the bottom of the flanged slab section.

• If \( a_1 > a_{max} \), compression reinforcement is required (ACI 9.3.3.1, 21.2.2, Fig 21.2.2b, 22.2.2.4.1) and is calculated as follows:

– The compressive force in the web concrete alone is given by:

\[
C_w = 0.85 f'_c b_w a_{max} \tag{ACI 22.2.2.4.1}
\]

Therefore the moment resisted by the concrete web and tension reinforcement is:

\[
M_{uc} = C_w \left(d - \frac{a_{max}}{2}\right) \phi
\]

and the moment resisted by compression and tension reinforcement is:

\[
M_{us} = M_{uw} - M_{uc}
\]

Therefore, the compression reinforcement is computed as:

\[
A'_s = \frac{M_{us}}{(f'_s - 0.85 f'_c)(d - d') \phi}, \text{ where}
\]
ETABS Reinforced Concrete Slab Design

\[ f'_{s} = E_{s} \varepsilon_{c_{\text{max}}} \left( \frac{c_{\text{max}} - d'}{c_{\text{max}}} \right) \leq f_{y} \quad \text{(ACI 9.2.1.2, 9.5.2.1, 20.2.2, 22.2.1.2)} \]

The tension reinforcement for balancing compression in the web concrete is:

\[ A_{s,2} = \frac{M_{\text{uc}}}{f_{y} \left[ d - \frac{a_{\text{max}}}{2} \right] \phi} \]

and the tension reinforcement for balancing the compression reinforcement is:

\[ A_{s,3} = \frac{M_{\text{uc}}}{f_{y} (d - d') \phi} \]

The total tension reinforcement is \( A_{s} = A_{s,1} + A_{s,2} + A_{s,3} \), and the total compression reinforcement is \( A'_{s} \). \( A_{s} \) is to be placed at the bottom and \( A'_{s} \) is to be placed at the top.

### 2.5.1.3 Minimum and Maximum Slab Reinforcement

The minimum flexural tension reinforcement required for each direction of a slab is given by the following limits (ACI 7.6.1.1, 8.6.1.1):

\[ A_{s,\text{min}} = 0.0020 \, bh \quad \text{for} \quad f_{y} < 60 \text{ ksi} \quad \text{(ACI Table 7.6.1.1, Table 8.6.1.1)} \]

\[ A_{s,\text{min}} = 0.0018 \, bh \quad \text{for} \quad f_{y} = 60 \text{ ksi} \quad \text{(ACI Table 7.6.1.1, Table 8.6.1.1)} \]

\[ A_{s,\text{min}} = \frac{0.0018 \times 60000}{f_{y}} \, bh \quad \text{for} \quad f_{y} > 60 \text{ ksi}(ACI \ \text{Table 7.6.1.1, Table 8.6.1.1}) \]

In addition, an upper limit on both the tension reinforcement and compression reinforcement has been imposed to be 0.04 times the gross cross-sectional area.

### 2.5.2 Design Slab Shear Reinforcement

The shear reinforcement is designed for each load combination at each station along the design strip. In designing the shear reinforcement for a particular strip,
for a particular load combination, at a particular station due to the slab major shear, the following steps are involved:

- Determine the factored shear force, $V_u$.
- Determine the shear force, $V_c$, that can be resisted by the concrete.
- Determine the shear reinforcement required to carry the balance.

The following three sections describe in detail the algorithms associated with these steps.

### 2.5.2.1 Determine Factored Shear Force

In the design of the slab shear reinforcement, the shear forces for each load combination at a particular design strip station are obtained by factoring the corresponding shear forces for different load cases, with the corresponding load combination factors.

### 2.5.2.2 Determine Concrete Shear Capacity

The shear force carried by the concrete, $V_c$, is calculated as:

$$ V_c = 2\lambda \sqrt{f_c'} b_u d $$

(ACI 22.5.1.2)

A limit is imposed on the value of $\sqrt{f_c'}$ as $f_c' \leq 100$

(ACI 22.5.3.1)

The value of $\lambda$ should be specified in the material property definition.

### 2.5.2.3 Determine Required Shear Reinforcement

The shear force is limited to a maximum of:

$$ V_{\text{max}} = V_c + (8\sqrt{f_c'}) b_u d $$

(ACI 22.5.1.2)

Given $V_u$, $V_c$, and $V_{\text{max}}$, the required shear reinforcement is calculated as follows where, $\phi$, the strength reduction factor, is 0.75 (ACI 9.3.2.3). The flexural reinforcement strength, $f_{yt}$, is limited to 60 ksi (ACI 11.5.2) even if the material property is defined with a higher value.
ETABS Reinforced Concrete Slab Design

- If $V_u \leq \phi V_c$, 
  \[
  \frac{A_v}{s} = 0 \quad \text{(ACI 9.6.3.1)}
  \]

- If $\phi V_c < V_u \leq \phi V_{\text{max}}$, 
  \[
  \frac{A_v}{s} = \frac{(V_u - \phi V_c)}{\phi f_{yt} d} \quad \text{(ACI 22.5.1.1, 22.5.10.1, 20.5.10.5.3)}
  \]

- If $V_u > \phi V_{\text{max}}$, a failure condition is declared. \quad \text{(ACI 22.5.1.2)}

If $V_u$ exceeds the maximum permitted value of $\phi V_{\text{max}}$, the concrete section should be increased in size (ACI 22.5.1.2).

The minimum shear reinforcement given by ACI 9.6.3.3.

\[
\frac{A_v}{s} \geq \max \left( 0.75 \sqrt{\frac{f_c'}{f_{yt}}} b_w, \frac{50 b_w}{f_{yt}} \right) \quad \text{(ACI 9.6.3.3, Table 9.6.3.3)}
\]

The maximum of all of the calculated $A_v/s$ values obtained from each load combination is reported along with the controlling shear force and associated load combination.

The slab shear reinforcement requirements considered by the program are based purely on shear strength considerations. Any minimum stirrup requirements to satisfy spacing and volumetric considerations must be investigated independently of the program by the user.

2.5.3 Check for Punching Shear

The algorithm for checking punching shear is detailed in the section entitled “Slab Punching Shear Check” in the Chapter 1. Only the code-specific items are described in the following sections.

2.5.3.1 Critical Section for Punching Shear

The punching shear is checked on a critical section at a distance of $d/2$ from the face of the support (ACI 22.6.4.2). For rectangular columns and concentrated
loads, the critical area is taken as a rectangular area with the sides parallel to the sides of the columns or the point loads (ACI 22.6.4.3). Figure 2-3 shows the auto punching perimeters considered by ETABS for the various column shapes. The column location (i.e., interior, edge or corner) and the punching perimeter may be overwritten using the Punching Check Overwrites.

![Figure 2-3 Punching Shear Perimeters](image)

**2.5.3.2 Transfer of Unbalanced Moment**

The fraction of unbalanced moment transferred by flexure is taken to be \( \gamma_f M_{sc} \) and the fraction of unbalanced moment transferred by eccentricity of shear is taken to be \( \gamma_v M_{sc} \).

\[
\gamma_f = \frac{1}{1 + (2/3) \sqrt{b_1/b_2}} \quad \text{(ACI 8.4.2.3)}
\]

\[
\gamma_v = 1 - \gamma_f \quad \text{(ACI 8.4.4.2.2)}
\]
For reinforced concrete slabs, $\gamma_f$ is permitted to increase to the maximum modified values provided in ACI Table 8.4.2.3.4 provided that the limitations on $v_{ug}$ and $\varepsilon_t$ given in ACI Table 8.4.2.3.4 are satisfied.

<table>
<thead>

</tr>
<tr>
<td>Interior column</td>
<td>Either direction</td>
<td>$\leq 0.4\psi v_c$</td>
<td>$\geq 0.010$</td>
<td>$\gamma_f = \frac{1.25}{1 + (2/3)\sqrt{b_1/b_2}} \leq 1.0$</td>
</tr>
</tbody>
</table>

where $b_1$ is the width of the critical section measured in the direction of the span and $b_2$ is the width of the critical section measured in the direction perpendicular to the span.

### 2.5.3.3 Determine Concrete Capacity

The concrete punching shear stress capacity is taken as the minimum of the following three limits:

$$v_c = \min \left\{ \left( 2 + \frac{4}{\beta_c} \right) \lambda \sqrt{f'_c} , \left( 2 + \frac{\alpha d}{b_o} \right) \lambda \sqrt{f'_c} , 4\lambda \sqrt{f'_c} \right\} (ACI 22.6.5.2)$$
where, $\beta$ is the ratio of the maximum to the minimum dimensions of the critical section, $b_o$ is the perimeter of the critical section, and $\alpha_s$ is a scale factor based on the location of the critical section.

\[
\alpha_s = \begin{cases} 
40 & \text{for interior columns,} \\
30 & \text{for edge columns, and} \\
20 & \text{for corner columns.} 
\end{cases} 
\] (ACI 22.6.65.3)

A limit is imposed on the value of $\sqrt{f'_c}$ as:

\[
\sqrt{f'_c} \leq 100 
\] (ACI 22.5.3.1)

### 2.5.3.4 Computation of Maximum Shear Stress

Given the punching shear force and the fractions of moments transferred by eccentricity of shear about the two axes, the shear stress is computed assuming linear variation along the perimeter of the critical section.

\[
\nu_U = \frac{V_U}{b_o d} + \frac{\gamma v}{I_{22} I_{33} - I_{23}^2} \left[ M_{U2} - V_U (y_2 - y_1) - M_{U3} (x_2 - x_1) \right] 
\] Eq. 1

\[
I_{22} = \sum_{\text{sides}=1}^{n} \bar{T}_{22}, \text{ where "sides" refers to the sides of the critical section for punching shear} \quad \text{Eq. 2}
\]

\[
I_{33} = \sum_{\text{sides}=1}^{n} \bar{T}_{33}, \text{ where "sides" refers to the sides of the critical section for punching shear} \quad \text{Eq. 3}
\]

\[
I_{23} = \sum_{\text{sides}=1}^{n} \bar{T}_{23}, \text{ where "sides" refers to the sides of the critical section for punching shear} \quad \text{Eq. 4}
\]
The equations for $T_{22}, T_{33},$ and $T_{23}$ are different depending on whether the side of the critical section for punching shear being considered is parallel to the 2-axis or parallel to the 3-axis. Refer to Figure 2-4.

$$T_{22} = Ld(y_2 - y_3)^2$$, for the side of the critical section parallel to the 2-axis  
Eq. 5a

$$T_{22} = \frac{Ld^3}{12} + \frac{dL^3}{12} + Ld(y_2 - y_3)^2$$, for the side of the critical section parallel to the 3-axis  
Eq. 5b

$$T_{33} = \frac{Ld^3}{12} + \frac{dL^3}{12} + Ld(x_2 - x_3)^2$$, for the side of the critical section parallel to the 2-axis  
Eq. 6a

$$T_{33} = Ld(x_2 - x_1)^2$$, for the side of the critical section parallel to the 3-axis  
Eq. 6b

$$T_{23} = Ld(x_2 - x_3)(y_2 - y_3)$$, for side of critical section parallel to 2-axis or 3-axis  
Eq. 7

**NOTE:** $T_{23}$ is explicitly set to zero for corner condition.
where,

\( b_0 \) = Perimeter of the critical section for punching shear

\( d \) = Effective depth at the critical section for punching shear based on the average of \( d \) for 2 direction and \( d \) for 3 direction

\( I_{22} \) = Moment of inertia of the critical section for punching shear about an axis that is parallel to the local 2-axis

\( I_{33} \) = Moment of inertia of the critical section for punching shear about an axis that is parallel to the local 3-axis

\( I_{23} \) = Product of the inertia of the critical section for punching shear with respect to the 2 and 3 planes
$L$ = Length of the side of the critical section for punching shear currently being considered

$M_{U2}$ = Moment about the line parallel to the 2-axis at the center of the column (positive in accordance with the right-hand rule)

$M_{U3}$ = Moment about the line parallel to the 3-axis at the center of the column (positive in accordance with the right-hand rule)

$v_U$ = Punching shear stress

$V_U$ = Shear at the center of the column (positive upward)

$x_1, y_1$ = Coordinates of the column centroid

$x_2, y_2$ = Coordinates of the center of one side of the critical section for punching shear

$x_3, y_3$ = Coordinates of the centroid of the critical section for punching shear

$x_4, y_4$ = Coordinates of the location where stress is being calculated

$\gamma_{V2}$ = Percent of $M_{U2}$ resisted by shear

$\gamma_{V3}$ = Percent of $M_{U3}$ resisted by shear

2.5.3.5 **Determine Capacity Ratio**

Given the punching shear force and the fractions of moments transferred by eccentricity of shear about the two axes, the shear stress is computed assuming linear variation along the perimeter of the critical section. The ratio of the maximum shear stress and the concrete punching shear stress capacity is reported as the punching shear capacity ratio by ETABS. If this ratio exceeds 1.0, punching shear reinforcement is designed as described in the following section.

2.5.4 **Design Punching Shear Reinforcement**

The use of shear studs as shear reinforcement in slabs is permitted, provided that the effective depth of the slab is greater than or equal to 6 inches, and not less than 16 times the shear reinforcement bar diameter (ACI 22.6.7.1). If the slab
thickness does not meet these requirements, the punching shear reinforcement is not designed and the slab thickness should be increased by the user.

The algorithm for designing the required punching shear reinforcement is used when the punching shear capacity ratio exceeds unity. The Critical Section for Punching Shear and Transfer of Unbalanced Moment as described in the earlier sections remain unchanged. The design of punching shear reinforcement is described in the subsections that follow.

2.5.4.1 Determine Concrete Shear Capacity

The concrete punching shear stress capacity of a section with punching shear reinforcement is limited to:

\[ v_c \leq 2 \lambda \sqrt{f'_{cu}} \text{ for shear links} \quad (ACI 22.6.6.1) \]

\[ v_c \leq 3 \lambda \sqrt{f'_{cu}} \text{ for shear studs} \quad (ACI 22.6.6.1) \]

2.5.4.2 Determine Required Shear Reinforcement

The shear force is limited to a maximum of:

\[ V_{max} = 6 \sqrt{f'_{cu}} b_d \text{ for shear links} \quad (ACI 22.6.6.2) \]

\[ V_{max} = 8 \sqrt{f'_{cu}} b_d \text{ for shear studs} \quad (ACI 22.6.6.2) \]

Given \( V_u, V_c \), and \( V_{max} \), the required shear reinforcement is calculated as follows, where, \( \phi \), the strength reduction factor, is 0.75 (ACI 9.3.2.3).

\[ A_v = \frac{(V_u - \phi V_c)}{\phi f_{ys} d} \quad (ACI 22.5.1.1, 22.5.10.1, 20.5.10.5.3) \]

\[ A_v \geq \frac{2 \sqrt{f'_{cu}} b_d}{f_y} \text{ for shear studs} \]

- If \( V_u > \phi V_{max} \), a failure condition is declared. \quad (ACI 22.5.1.2)
• If $V_u$ exceeds the maximum permitted value of $\phi V_{\text{max}}$, the concrete section should be increased in size.

### 2.5.4.3 Determine Reinforcement Arrangement

Punching shear reinforcement in the vicinity of rectangular columns should be arranged on peripheral lines, i.e., lines running parallel to and at constant distances from the sides of the column. Figure 2-5 shows a typical arrangement of shear reinforcement in the vicinity of a rectangular interior, edge, and corner column.

#### Figure 2-5 Typical arrangement of shear studs and critical sections outside shear-reinforced zone

The distance between the column face and the first line of shear reinforcement shall not exceed $d/2$(ACI 8.7.6.3, Table 8.7.6.3) and the spacing between shear reinforcement shall not exceed $d/2$(ACI 8.7.6.3, Table 8.7.6.3). The spacing between adjacent shear reinforcement in the first line (perimeter) of shear reinforcement shall not exceed $2d$ measured in a direction parallel to the column face (ACI 8.7.6.3, Table 8.7.6.3).

Punching shear reinforcement is most effective near column corners where there are concentrations of shear stress. Therefore, the minimum number of lines of shear reinforcement is 4, 6, and 8, for corner, edge, and interior columns respectively.
2.5.4.4 Determine Reinforcement Diameter, Height, and Spacing

The punching shear reinforcement is most effective when the anchorage is close to the top and bottom surfaces of the slab. The cover of anchors should not be less than the minimum cover specified in 20.6.1.3 plus half of the diameter of the flexural reinforcement.

Punching shear reinforcement in the form of shear studs is generally available in 3/8-, 1/2-, 5/8-, and 3/4-inch diameters.

When specifying shear studs, the distance, $s_o$, between the column face and the first peripheral line of shear studs should not be smaller than 0.5$d$. The spacing between adjacent shear studs, $g$, at the first peripheral line of studs shall not exceed 2$d$, and in the case of studs in a radial pattern, the angle between adjacent stud rails shall not exceed 60 degrees. The limits of $s_o$ and the spacing, $s$, between the peripheral lines are specified as:

$$s_o \leq 0.5d$$  \hspace{1cm} (ACI 8.7.7.1.2)

$$s \begin{cases} 0.75d & \text{for } v_u \leq 6\phi \sqrt{f' c} \\ 0.50d & \text{for } v_u > 6\phi \sqrt{f' c} \end{cases}$$  \hspace{1cm} (ACI 8.7.7.1.2)

$$g \leq 2d$$  \hspace{1cm} (ACI 8.7.7.1.2)

The limits of $s_o$ and the spacing, $s$, between for the links are specified as:

$$s_o \leq 0.5d$$  \hspace{1cm} (ACI 8.7.6.3)

$$s \leq 0.50d$$  \hspace{1cm} (ACI 8.7.6.3)
This chapter describes in detail the various aspects of the concrete design procedure that is used by ETABS when the American code ACI 318-11 [ACI 2011] is selected. Various notations used in this chapter are listed in Table 3-1. For referencing to the pertinent sections or equations of the ACI code in this chapter, a prefix “ACI” followed by the section or equation number is used herein.

The design is based on user-specified load combinations. The program provides a set of default load combinations that should satisfy the requirements for the design of most building type structures.

English as well as SI and MKS metric units can be used for input. The code is based on inch-pound-second units. For simplicity, all equations and descriptions presented in this chapter correspond to inch-pound-second units unless otherwise noted.

3.2 Design Load Combinations

The design load combinations are the various combinations of the load cases for which the structure needs to be designed. For ACI 318-11, if a structure is subjected to dead (D), live (L), pattern live (PL), snow (S), wind (W), and earthquake (E) loads, and considering that wind and earthquake forces are reversible, the following load combinations may need to be considered (ACI 9.2.1):

1.4D  
1.2D + 1.6L  
1.2D + 1.6 (0.75 PL)  
0.9D ± 1.0W  
1.2D + 1.0L ± 1.0W  
0.9D ± 1.0E  
1.2D + 1.0L ± 1.0E  
1.2D + 1.6L ± 0.5S  
1.2D + 1.0L + 1.6S  
1.2D + 1.6S ± 0.5W  
1.2D + 1.0L + 0.5S ± 1.0W  
1.2D + 1.0L + 0.2S ± 1.0E
These are the default design load combinations in ETABS whenever the ACI 318-11 code is used. The user should use other appropriate load combinations if roof live load is treated separately, or if other types of loads are present.

3.3 **Limits on Material Strength**

The concrete compressive strength, \( f'_c \), should not be less than 2,500 psi (ACI 5.1.1). The upper limit of the reinforcement yield strength, \( f_y \), is taken as 80 ksi (ACI 9.4) and the upper limit of the reinforcement shear strength, \( f_{ys} \), is taken as 60 ksi (ACI 11.4.2).

If the input \( f'_c \) is less than 2,500 psi, ETABS continues to design the members based on the input \( f'_c \) and does not warn the user about the violation of the code. The user is responsible for ensuring that the minimum strength is satisfied.

3.4 **Strength Reduction Factors**

The strength reduction factors, \( \phi \), are applied to the specified strength to obtain the design strength provided by a member. The \( \phi \) factors for flexure, shear, and torsion are as follows:

\[
\phi = 0.90 \text{ for flexure (tension controlled)} \quad (ACI 9.3.2.1)
\]

\[
\phi = 0.75 \text{ for shear and torsion} \quad (ACI 9.3.2.3)
\]

These values can be overwritten; however, caution is advised.

3.5 **Slab Design**

ETABS slab design procedure involves defining sets of strips in two mutually perpendicular directions. The locations of the strips are usually governed by the locations of the slab supports. The axial force, moments and shears for a particular strip are recovered from the analysis (on the basis of the Wood-Armer technique), and a flexural design is carried out based on the ultimate strength design method.

The slab design procedure involves the following steps:
3.5.1 Design Flexural Reinforcement

For slabs, ETABS uses either design strips or the finite element based design to calculate the slab flexural reinforcement in accordance with the selected design code. For simplicity, only strip-by-strip design is document in the proceeding sections.

The design of the slab reinforcement for a particular strip is carried out at specific locations along the length of the strip. These locations correspond to the element boundaries. Controlling reinforcement is computed on either side of those element boundaries. The slab flexural design procedure for each load combination involves the following:

- Determine factored axial loads and moments for each slab strip.
- Design flexural reinforcement for the strip.

These two steps, described in the text that follows, are repeated for every load combination. The maximum reinforcement calculated for the top and bottom of the slab within each design strip, along with the corresponding controlling load combination, is obtained and reported.

3.5.1.1 Determine Factored Moments

In the design of flexural reinforcement of concrete slab, the factored moments for each load combination at a particular design strip are obtained by factoring the corresponding moments for different load cases, with the corresponding load factors.

The slab is then designed for the maximum positive and maximum negative factored moments obtained from all of the load combinations. Calculation of bottom reinforcement is based on positive design strip moments. In such cases, the slab
Chapter 03 - Design for ACI 318-11

may be designed as a rectangular or flanged slab section. Calculation of top reinforcement is based on negative design strip moments. In such cases, the slab may be designed as a rectangular or inverted flanged slab section.

3.5.1.2 Determine Required Flexural Reinforcement

In the flexural reinforcement design process, the program calculates both the tension and compression reinforcement. Compression reinforcement is added when the applied design moment exceeds the maximum moment capacity of a singly reinforced section. The user has the option of avoiding compression reinforcement by increasing the effective depth, the width, or the strength of the concrete. Note that the flexural reinforcement strength, $f_y$, is limited to 80 ksi (ACI 9.4), even if the material property is defined using a higher value.

The design procedure is based on the simplified rectangular stress block, as shown in Figure 3-1 (ACI 10.2). Furthermore, it is assumed that the net tensile strain in the reinforcement shall not be less than 0.005 (tension controlled) (ACI 10.3.4) when the concrete in compression reaches its assumed strain limit of 0.003. When the applied moment exceeds the moment capacity at this design condition, the area of compression reinforcement is calculated assuming that the additional moment will be carried by compression reinforcement and additional tension reinforcement.

The design procedure used by ETABS, for both rectangular and flanged sections (L- and T-shaped sections), is summarized in the text that follows. For reinforced concrete design where design ultimate axial compression load does not exceed $(0.1f'_cA_g)$ (ACI 10.3.5), axial force is ignored; hence, all slabs are designed for major direction flexure, shear, and torsion only. Axial compression greater than $(0.1f'_cA_g)$ and axial tensions are always included in flexural and shear design.

3.5.1.2.1 Design of uniform thickness slab

In designing for a factored negative or positive moment, $M_u$ (i.e., designing top or bottom reinforcement), the depth of the compression block is given by $a$ (see Figure 3-1), where,
\[
a = d - \sqrt{d^2 - \frac{2|M_u|}{0.85 f'_c \phi b}} \tag{ACI 10.2}
\]

and the value of \( \phi \) is taken as that for a tension-controlled section, which by default is 0.90 (ACI 9.3.2.1) in the preceding and the following equations.

The maximum depth of the compression zone, \( c_{\text{max}} \), is calculated based on the limitation that the tension reinforcement strain shall not be less than \( \varepsilon_s \), which is equal to 0.005 for tension controlled behavior (ACI 10.3.4):

\[
c_{\text{max}} = \frac{\varepsilon_{\text{cmax}}}{\varepsilon_{\text{cmax}} + \varepsilon_{\text{min}}} \cdot d \tag{ACI 10.2.2}
\]

*Figure 3-1 Uniform Thickness Slab Design*

where,

\[
\varepsilon_{\text{cmax}} = 0.003 \tag{ACI 10.2.3}
\]

\[
\varepsilon_{\text{min}} = 0.005 \tag{ACI 10.3.4}
\]
The maximum allowable depth of the rectangular compression block, \(a_{\text{max}}\), is given by:

\[a_{\text{max}} = \beta_1 c_{\text{max}}\]  

(ACI 10.2.7.1)

where \(\beta_1\) is calculated as:

\[\beta_1 = 0.85 - 0.05 \left( \frac{f_e' - 4000}{1000} \right), \quad 0.65 \leq \beta_1 \leq 0.85\]  

(ACI 10.2.7.3)

- If \(a \leq a_{\text{max}}\) (ACI 10.3.4), the area of tension reinforcement is then given by:

\[A_y = \frac{M_u}{\phi f_y \left( d - \frac{a}{2} \right)}\]

This reinforcement is to be placed at the bottom if \(M_u\) is positive, or at the top if \(M_u\) is negative.

- If \(a > a_{\text{max}}\), compression reinforcement is required (ACI 10.3.5.1) and is calculated as follows:

  - The compressive force developed in the concrete alone is given by:

\[C = 0.85 f_e' b a_{\text{max}}\]  

(ACI 10.2.7.1)

and the moment resisted by concrete compression and tension reinforcement is:

\[M_{uc} = \phi C \left( d - \frac{a_{\text{max}}}{2} \right)\]  

(ACI 9.3.2.1)

- Therefore the moment required to be resisted by compression reinforcement and tension reinforcement is:

\[M_{uy} = M_u - M_{uc}\]

- The required compression reinforcement is given by:
ETABS Reinforced Concrete Design

\[ A'_s = \frac{M_{ux}}{\phi \left( f'_{s} - 0.85 f'_{c} \right) (d - d')} \], where

\[ f'_{s} = E_s \varepsilon_{c_{max}} \left[ \frac{c_{max} - d'}{c_{max}} \right] \leq f_y \]  

(ACI 10.2.2, 10.2.3, 10.2.4)

The required tension reinforcement for balancing the compression in the concrete is:

\[ A_{s1} = \frac{M_{uc}}{\phi f_y \left( d - a_{max} \right)} \]

and the tension reinforcement for balancing the compression reinforcement is given by:

\[ A_{s2} = \frac{M_{ux}}{\phi f_y \left( d - d' \right)} \]

Therefore, the total tension reinforcement is \( A_s = A_{s1} + A_{s2} \), and the total compression reinforcement is \( A'_s \). \( A_s \) is to be placed at the bottom and \( A'_s \) is to be placed at the top if \( M_u \) is positive, and vice versa if \( M_u \) is negative.

3.5.1.2.2 Design of nonuniform thickness slab

In designing a nonuniform thickness slab, a simplified stress block, as shown in Figure 3-2, is assumed if the flange is under compression, i.e., if the moment is positive. If the moment is negative, the flange comes under tension, and the flange is ignored. In that case, a simplified stress block similar to that shown in Figure 3-1 is assumed on the compression side.
3.5.1.2.2.1 Flanged Slab Under Negative Moment

In designing for a factored negative moment, $M_u$ (i.e., designing top reinforcement), the calculation of the reinforcement area is exactly the same as described previously, i.e., no flanged data is used.

3.5.1.2.2.2 Flanged Slab Under Positive Moment

If $M_u > 0$, the depth of the compression block is given by:

$$a = d - \frac{2 M_u}{0.85 f'_c \phi b_f}$$

(ACI 10.2)

where, the value of $\phi$ is taken as that for a tension-controlled section, which by default is 0.90 (ACI 9.3.2.1) in the preceding and the following equations.

The maximum depth of the compression zone, $c_{\text{max}}$, is calculated based on the limitation that the tension reinforcement strain shall not be less than $\varepsilon_{\text{min}}$, which is equal to 0.005 for tension controlled behavior (ACI 10.3.4):
ETABS Reinforced Concrete Design

\[ c_{\text{max}} = \frac{\epsilon_{c, \text{max}}}{\epsilon_{c, \text{max}} + \epsilon_{s, \text{min}}} \cdot d \]  

(ACI 10.2.2)

where,

\[ \epsilon_{c, \text{max}} = 0.003 \]  

(ACI 10.2.3)

\[ \epsilon_{s, \text{min}} = 0.005 \]  

(ACI 10.3.4)

The maximum allowable depth of the rectangular compression block, \( a_{\text{max}} \), is given by:

\[ a_{\text{max}} = \beta_1 c_{\text{max}} \]  

(ACI 10.2.7.1)

where \( \beta_1 \) is calculated as:

\[ \beta_1 = 0.85 - 0.05 \left( \frac{f'_{\text{c}} - 4000}{1000} \right), \quad 0.65 \leq \beta_1 \leq 0.85 \]  

(ACI 10.2.7.3)

- If \( a \leq h_f \), the subsequent calculations for \( A_s \) are exactly the same as previously defined for the rectangular slab design. However, in this case, the width of the slab is taken as \( b_f \). Compression reinforcement is required if \( a > a_{\text{max}} \).

- If \( a > h_f \), the calculation for \( A_s \) has two parts. The first part is for balancing the compressive force from the flange, \( C_f \), and the second part is for balancing the compressive force from the web, \( C_w \), as shown in Figure 3-2. \( C_f \) is given by:

\[ C_f = 0.85 f'_{\text{c}} \left( b_f - b_w \right) \min \left( h_f, a_{\text{max}} \right) \]  

(ACI 10.2.7.1)

Therefore, \( A_{sf} = \frac{C_f}{f_y} \) and the portion of \( M_u \) that is resisted by the flange is given by:

\[ M_{uf} = \phi C_f \left( d - \frac{\min \left( h_f, a_{\text{max}} \right)}{2} \right) \]  

(ACI 9.3.2.1)

Again, the value for \( \phi \) is 0.90 by default. Therefore, the balance of the moment, \( M_u \), to be carried by the web is:
$M_{uw} = M_u - M_{af}$

The web is a rectangular section with dimensions $b_w$ and $d$, for which the design depth of the compression block is recalculated as:

$$a_1 = d - \sqrt{d^2 - \frac{2M_{uw}}{0.85f'_c \phi b_w}}$$  \hspace{1cm} (ACI 10.2)

- If $a_1 \leq a_{\max}$ (ACI 10.3.4), the area of tension reinforcement is then given by:

$$A_{s2} = \frac{M_{uw}}{\phi f_y \left(d - \frac{a_1}{2}\right)}$$

$$A_s = A_{s1} + A_{s2}$$

This reinforcement is to be placed at the bottom of the flanged slab.

- If $a_1 > a_{\max}$, compression reinforcement is required (ACI 10.3.5.1) and is calculated as follows:

  - The compressive force in the web concrete alone is given by:

$$C_w = 0.85 f'_c b_w a_{\max}$$  \hspace{1cm} (ACI 10.2.7.1)

Therefore the moment resisted by the concrete web and tension reinforcement is:

$$M_{wc} = C_w \left(d - \frac{a_{\max}}{2}\right) \phi$$

and the moment resisted by compression and tension reinforcement is:

$$M_{ws} = M_{uw} - M_{wc}$$

Therefore, the compression reinforcement is computed as:

$$A'_s = \frac{M_{ws}}{(f'_c - 0.85f'_c)(d - d') \phi}, \quad \text{where}$$
The tension reinforcement for balancing compression in the web concrete is:

\[
A_{s2} = \frac{M_{uc}}{f_y \left( d - \frac{a_{max}}{2} \right) \phi}
\]

and the tension reinforcement for balancing the compression reinforcement is:

\[
A_{s3} = \frac{M_{ui}}{f_y (d - d') \phi}
\]

The total tension reinforcement is \(A_s = A_{s1} + A_{s2} + A_{s3}\), and the total compression reinforcement is \(A'_s\). \(A_s\) is to be placed at the bottom and \(A'_s\) is to be placed at the top.

### 3.5.1.1 Minimum and Maximum Slab Reinforcement

The minimum flexural tension reinforcement required for each direction of a slab is given by the following limits (ACI 7.12.2, 13.3.1):

\[
A_{s,\text{min}} = \begin{cases} 
0.0020 \ bh & \text{for } f_y = 40 \text{ ksi or 50 ksi} \\
0.0018 \ bh & \text{for } f_y = 60 \text{ ksi} \\
\frac{0.0018 \times 60000}{f_y} \ bh & \text{for } f_y > 60 \text{ ksi}
\end{cases}
\] (ACI 7.12.2.1(a), (b), (c))

In addition, an upper limit on both the tension reinforcement and compression reinforcement has been imposed to be 0.04 times the gross cross-sectional area.

### 3.5.2 Design Slab Shear Reinforcement

The shear reinforcement is designed for each load combination at each station along the design strip. In designing the shear reinforcement for a particular strip,
for a particular load combination, at a particular station due to the slab major shear, the following steps are involved:

- Determine the factored shear force, $V_u$.
- Determine the shear force, $V_c$, that can be resisted by the concrete.
- Determine the shear reinforcement required to carry the balance.

The following three sections describe in detail the algorithms associated with these steps.

3.5.2.1 Determine Factored Shear Force

In the design of the slab shear reinforcement, the shear forces for each load combination at a particular design strip station are obtained by factoring the corresponding shear forces for different load cases, with the corresponding load combination factors.

3.5.2.2 Determine Concrete Shear Capacity

The shear force carried by the concrete, $V_c$, is calculated as:

$$V_c = 2\lambda \sqrt{f'_{c}} b_u d$$

(ACI 11.2.1.2)

A limit is imposed on the value of $\sqrt{f'_{c}}$ as $f'_{c} \leq 100$ (ACI 11.1.2)

The value of $\lambda$ should be specified in the material property definition.

3.5.2.3 Determine Required Shear Reinforcement

The shear force is limited to a maximum of:

$$V_{\text{max}} = V_c + (8\sqrt{f'_{c}}) b_u d$$

(ACI 11.4.7.9)

Given $V_u$, $V_c$, and $V_{\text{max}}$, the required shear reinforcement is calculated as follows where, $\phi$, the strength reduction factor, is 0.75 (ACI 9.3.2.3). The flexural reinforcement strength, $f_{yt}$, is limited to 60 ksi (ACI 11.5.2) even if the material property is defined with a higher value.
ETABS Reinforced Concrete Design

- If $V_u \leq \phi V_c$,

$$\frac{A_v}{s} = 0 \quad (ACI\ 11.4.6.1)$$

- If $\phi V_c < V_u \leq \phi V_{\text{max}}$,

$$\frac{A_v}{s} = \frac{(V_u - \phi V_c)}{\phi f_{\text{yt}} d} \quad (ACI\ 11.4.7.1, 11.4.7.2)$$

- If $V_u > \phi V_{\text{max}}$, a failure condition is declared. \hspace{1cm} (ACI\ 11.4.7.9)

If $V_u$ exceeds the maximum permitted value of $\phi V_{\text{max}}$, the concrete section should be increased in size (ACI 11.4.7.9).

The minimum shear reinforcement given by ACI 11.4.6.3 is not enforced (ACI 11.4.6.1).

$$\frac{A_v}{s} \geq \max \left( \frac{0.75 \sqrt{f_{\text{ct}}} b_w}{f_{\text{yt}}}, \frac{50 b_w}{f_{\text{yt}}} \right) \quad (ACI\ 11.4.6.3)$$

The maximum of all of the calculated $A_v/s$ values obtained from each load combination is reported along with the controlling shear force and associated load combination.

The slab shear reinforcement requirements considered by the program are based purely on shear strength considerations. Any minimum stirrup requirements to satisfy spacing and volumetric considerations must be investigated independently of the program by the user.

3.5.3 Check for Punching Shear

The algorithm for checking punching shear is detailed in the section entitled “Slab Punching Shear Check” in the Chapter 1. Only the code-specific items are described in the following sections.
3.5.3.1 Critical Section for Punching Shear

The punching shear is checked on a critical section at a distance of $d/2$ from the face of the support (ACI 11.11.1.2). For rectangular columns and concentrated loads, the critical area is taken as a rectangular area with the sides parallel to the sides of the columns or the point loads (ACI 11.11.1.3). Figure 3-3 shows the auto punching perimeters considered by ETABS for the various column shapes. The column location (i.e., interior, edge, corner) and the punching perimeter may be overwritten using the Punching Check Overwrites.

![Figure 3-3 Punching Shear Perimeters](image)

3.5.3.2 Transfer of Unbalanced Moment

The fraction of unbalanced moment transferred by flexure is taken to be $\gamma_f M_u$ and the fraction of unbalanced moment transferred by eccentricity of shear is taken to be $\gamma_v M_u$.

$$\gamma_f = \frac{1}{1 + \left(\frac{2}{3}\right)\sqrt{\frac{b_1}{b_2}}}$$  \hspace{1cm} (ACI 13.5.3.2)
\[ \gamma_v = 1 - \gamma_f \]  
\text{(ACI 13.5.3.1)}

For flat plates, \( \gamma_v \) is determined from the following equations taken from ACI 421.2R-07 Seismic Design of Punching Shear Reinforcement in Flat Plates [ACI 2007].

For interior columns,

\[ \gamma_{vx} = 1 - \frac{1}{1 + (2/3) \sqrt{l_y/l_x}} \]  
\text{(ACI 421.2 C-11)}

\[ \gamma_{vy} = 1 - \frac{1}{1 + (2/3) \sqrt{l_x/l_y}} \]  
\text{(ACI 421.2 C-12)}

For edge columns,

\[ \gamma_{vx} = \text{same as for interior columns} \]  
\text{(ACI 421.2 C-13)}

\[ \gamma_{vy} = 1 - \frac{1}{1 + (2/3) \sqrt{l_x/l_y} - 0.2} \]  
\text{(ACI 421.2 C-14)}

\[ \gamma_{vy} = 0 \text{ when } l_x/l_y \leq 0.2 \]

For corner columns,

\[ \gamma_{vx} = 0.4 \]  
\text{(ACI 421.2 C-15)}

\[ \gamma_{vy} = \text{same as for edge columns} \]  
\text{(ACI 421.2 C-16)}

\textbf{NOTE:} Program uses ACI 421.2-12 and ACI 421.2-15 equations in lieu of ACI 421.2 C-14 and ACI 421.2 C-16 which are currently NOT enforced.

where \( b_1 \) is the width of the critical section measured in the direction of the span and \( b_2 \) is the width of the critical section measured in the direction perpendicular to the span. The values \( l_x \) and \( l_y \) are the projections of the shear-critical section onto its principal axes, \( x \) and \( y \), respectively.
3.5.3.3 Determine Concrete Capacity

The concrete punching shear stress capacity is taken as the minimum of the following three limits:

\[
v_c = \min \left( \left( \frac{2 + \frac{4}{\beta_c}}{\lambda} \sqrt{f'_c} \right), \left( \frac{2 + \frac{\alpha_s d}{b_o}}{\lambda} \sqrt{f'_c} \right), 4\lambda \sqrt{f'_c} \right)
\]

where, \( \beta_c \) is the ratio of the maximum to the minimum dimensions of the critical section, \( b_o \) is the perimeter of the critical section, and \( \alpha_s \) is a scale factor based on the location of the critical section.

\[
\alpha_s = \begin{cases} 
40 & \text{for interior columns}, \\
30 & \text{for edge columns}, \\
20 & \text{for corner columns}.
\end{cases}
\]

A limit is imposed on the value of \( \sqrt{f'_c} \) as:

\[
\sqrt{f'_c} \leq 100
\] (ACI 11.1.2)

3.5.3.4 Computation of Maximum Shear Stress

Given the punching shear force and the fractions of moments transferred by eccentricity of shear about the two axes, the shear stress is computed assuming linear variation along the perimeter of the critical section.

\[
v_u = \frac{V_U}{b_o d} + \frac{\gamma V_3 [M_{U2} - V_U (y_3 - y_1)] [I_{33} (y_4 - y_3) - I_{23} (x_4 - x_3)]}{I_{22} I_{33} - I_{23}^2} - \frac{\gamma V_3 [M_{U3} - V_U (x_3 - x_1)] [I_{22} (x_4 - x_3) - I_{23} (y_4 - y_3)]}{I_{22} I_{33} - I_{23}^2}
\]

Eq. 1
\[ I_{22} = \sum_{sides=1}^{n} T_{22}, \text{ where } "sides" \text{ refers to the sides of the critical section for punching shear} \tag{Eq. 2} \]

\[ I_{33} = \sum_{sides=1}^{n} T_{33}, \text{ where } "sides" \text{ refers to the sides of the critical section for punching shear} \tag{Eq. 3} \]

\[ I_{23} = \sum_{sides=1}^{n} T_{23}, \text{ where } "sides" \text{ refers to the sides of the critical section for punching shear} \tag{Eq. 4} \]

The equations for \( T_{22}, T_{33}, \text{ and } T_{23} \) are different depending on whether the side of the critical section for punching shear being considered is parallel to the 2-axis or parallel to the 3-axis. Refer to Figure 3-4.

\[ T_{22} = Ld (y^2 - y^3)^2, \text{ for the side of the critical section parallel to the 2-axis} \tag{Eq. 5a} \]

\[ T_{22} = \frac{Ld^3}{12} + \frac{dd^3}{12} + Ld (y^2 - y^3)^2, \text{ for the side of the critical section parallel to the 3-axis} \tag{Eq. 5b} \]

\[ T_{33} = \frac{Ld^3}{12} + \frac{dd^3}{12} + Ld (x^2 - x^3)^2, \text{ for the side of the critical section parallel to the 2-axis} \tag{Eq. 6a} \]

\[ T_{33} = Ld (x^2 - x^3)^2, \text{ for the side of the critical section parallel to the 3-axis} \tag{Eq. 6b} \]
\[ T_{23} = Ld(x_2 - x_3)(y_2 - y_3) \]

**Equation 7**

**NOTE:** \( T_{23} \) is explicitly set to zero for corner condition.

where,

- \( b_0 \) = Perimeter of the critical section for punching shear
- \( d \) = Effective depth at the critical section for punching shear based on the average of \( d \) for 2 direction and \( d \) for 3 direction
- \( I_{22} \) = Moment of inertia of the critical section for punching shear about an axis that is parallel to the local 2-axis
3.5.3.5  **Determine Capacity Ratio**

Given the punching shear force and the fractions of moments transferred by eccentricity of shear about the two axes, the shear stress is computed assuming linear variation along the perimeter of the critical section. The ratio of the maximum shear stress and the concrete punching shear stress capacity is reported as the punching shear capacity ratio by ETABS. If this ratio exceeds 1.0, punching shear reinforcement is designed as described in the following section.
3.5.4 Design Punching Shear Reinforcement

The use of shear studs as shear reinforcement in slabs is permitted, provided that the effective depth of the slab is greater than or equal to 6 inches, and not less than 16 times the shear reinforcement bar diameter (ACI 11.11.3). If the slab thickness does not meet these requirements, the punching shear reinforcement is not designed and the slab thickness should be increased by the user.

The algorithm for designing the required punching shear reinforcement is used when the punching shear capacity ratio exceeds unity. The Critical Section for Punching Shear and Transfer of Unbalanced Moment as described in the earlier sections remain unchanged. The design of punching shear reinforcement is described in the subsections that follow.

3.5.4.1 Determine Concrete Shear Capacity

The concrete punching shear stress capacity of a section with punching shear reinforcement is limited to:

\[ v_c \leq 2\lambda f'_c \] for shear links \hspace{1cm} (ACI 11.11.3.1)

\[ v_c \leq 3\lambda f'_c \] for shear studs \hspace{1cm} (ACI 11.11.5.1)

3.5.4.2 Determine Required Shear Reinforcement

The shear force is limited to a maximum of:

\[ V_{\text{max}} = 6 f'_c b_d \] for shear links \hspace{1cm} (ACI 11.11.3.2)

\[ V_{\text{max}} = 8 f'_c b_d \] for shear studs \hspace{1cm} (ACI 11.11.5.1)

Given \( V_u \), \( V_c \), and \( V_{\text{max}} \), the required shear reinforcement is calculated as follows, where, \( \phi \), the strength reduction factor, is 0.75 (ACI 9.3.2.3).

\[
\frac{A_s}{s} = \frac{(V_u - \phi V_c)}{\phi f'_{s}} \] \hspace{1cm} (ACI 11.4.7.1, 11.4.7.2)
\[ \frac{A_v}{s} \geq \frac{2 \sqrt{f'_c b_o}}{f'_{y}} \text{ for shear studs} \quad \text{(ACI 11.11.5.1)} \]

- If \( V_u > \phi V_{\text{max}} \), a failure condition is declared. \quad \text{(ACI 11.11.3.2)}
- If \( V_u \) exceeds the maximum permitted value of \( \phi V_{\text{max}} \), the concrete section should be increased in size.

### 3.5.4.3 Determine Reinforcement Arrangement

Punching shear reinforcement in the vicinity of rectangular columns should be arranged on peripheral lines, i.e., lines running parallel to and at constant distances from the sides of the column. Figure 3-6 shows a typical arrangement of shear reinforcement in the vicinity of a rectangular interior, edge, and corner column.

![Typical Stud Rail](image)

**Figure 3-6 Typical arrangement of shear studs and critical sections outside shear-reinforced zone**

The distance between the column face and the first line of shear reinforcement shall not exceed \( d/2 \) (ACI R11.11.3.3, 11.11.5.2). The spacing between adjacent shear reinforcement in the first line (perimeter) of shear reinforcement shall not exceed \( 2d \) measured in a direction parallel to the column face (ACI 11.11.3.3).

Punching shear reinforcement is most effective near column corners where there are concentrations of shear stress. Therefore, the minimum number of lines of
shear reinforcement is 4, 6, and 8, for corner, edge, and interior columns respectively.

3.5.4.4 Determine Reinforcement Diameter, Height, and Spacing

The punching shear reinforcement is most effective when the anchorage is close to the top and bottom surfaces of the slab. The cover of anchors should not be less than the minimum cover specified in ACI 7.7 plus half of the diameter of the flexural reinforcement.

Punching shear reinforcement in the form of shear studs is generally available in 3/8-, 1/2-, 5/8-, and 3/4-inch diameters.

When specifying shear studs, the distance, \( s_o \), between the column face and the first peripheral line of shear studs should not be smaller than 0.5\( d \). The spacing between adjacent shear studs, \( g \), at the first peripheral line of studs shall not exceed 2\( d \), and in the case of studs in a radial pattern, the angle between adjacent stud rails shall not exceed 60 degrees. The limits of \( s_o \) and the spacing, \( s \), between the peripheral lines are specified as:

\[
s_o \leq 0.5d \\
\frac{s}{d} \leq \begin{cases} 
0.75 & \text{for } v_u \leq 6\phi \sqrt{f'_c} \\
0.50 & \text{for } v_u > 6\phi \sqrt{f'_c}
\end{cases} \\
g \leq 2d
\]

The limits of \( s_o \) and the spacing, \( s \), between for the links are specified as:

\[
s_o \leq 0.5d \\
s \leq 0.50d
\]
Chapter 4
Design for ACI 318-08

This chapter describes in detail the various aspects of the concrete design procedure that is used by ETABS when the American code ACI 318-08 [ACI 2008] is selected. Various notations used in this chapter are listed in Table 4-1. For referencing to the pertinent sections or equations of the ACI code in this chapter, a prefix “ACI” followed by the section or equation number is used herein.

The design is based on user-specified load combinations. The program provides a set of default load combinations that should satisfy the requirements for the design of most building type structures.

English as well as SI and MKS metric units can be used for input. The code is based on inch-pound-second units. For simplicity, all equations and descriptions presented in this chapter correspond to inch-pound-second units unless otherwise noted.

### 4.2 Design Load Combinations

The design load combinations are the various combinations of the load cases for which the structure needs to be designed. For ACI 318-08, if a structure is subjected to dead (D), live (L), pattern live (PL), snow (S), wind (W), and earthquake (E) loads, and considering that wind and earthquake forces are reversible, the following load combinations may need to be considered (ACI 9.2.1):

- 1.4D (ACI 9-1)
- 1.2D + 1.6L (ACI 9-2)
- 1.2D + 1.6 (0.75 PL) (ACI 13.7.6.3, 9-2)
- 0.9D ± 1.6W (ACI 9-6)
- 1.2D + 1.0L ± 1.6W (ACI 9-4)
- 0.9D ± 1.0E (ACI 9-7)
- 1.2D + 1.0L ± 1.0E (ACI 9-5)
- 1.2D + 1.6L + 0.5S (ACI 9-2)
- 1.2D + 1.0L + 1.6S (ACI 9-3)
- 1.2D + 1.6S ± 0.8W (ACI 9-3)
- 1.2D + 1.0L + 0.5S ± 1.6W (ACI 9-4)
- 1.2D + 1.0L + 0.2S ± 1.0E (ACI 9-5)
These are the default design load combinations in ETABS whenever the ACI 318-08 code is used. The user should use other appropriate load combinations if roof live load is treated separately, or if other types of loads are present.

### 4.3 Limits on Material Strength

The concrete compressive strength, $f'_c$, should not be less than 2,500 psi (ACI 5.1.1). If the input $f'_c$ is less than 2,500 psi, ETABS continues to design the members based on the input $f'_c$ and does not warn the user about the violation of the code. The user is responsible for ensuring that the minimum strength is satisfied.

### 4.4 Strength Reduction Factors

The strength reduction factors, $\phi$, are applied to the specified strength to obtain the design strength provided by a member. The $\phi$ factors for flexure, shear, and torsion are as follows:

\[
\phi = 0.90 \text{ for flexure (tension controlled)} \\
\phi = 0.75 \text{ for shear and torsion}
\]

These values can be overwritten; however, caution is advised.

### 4.5 Slab Design

ETABS slab design procedure involves defining sets of strips in two mutually perpendicular directions. The locations of the strips are usually governed by the locations of the slab supports. The axial force, moments and shears for a particular strip are recovered from the analysis (on the basis of the Wood-Armer technique), and a flexural design is carried out based on the ultimate strength design method.

The slab design procedure involves the following steps:

- Design flexural reinforcement
ETABS Reinforced Concrete Design

- Design shear reinforcement
- Punching check

4.5.1 Design Flexural Reinforcement

For slabs, ETABS uses either design strips or the finite element based design to calculate the slab flexural reinforcement in accordance with the selected design code. For simplicity, only strip-by-strip design is document in the proceeding sections.

The design of the slab reinforcement for a particular strip is carried out at specific locations along the length of the strip. These locations correspond to the element boundaries. Controlling reinforcement is computed on either side of those element boundaries. The slab flexural design procedure for each load combination involves the following:

- Determine factored axial loads and moments for each slab strip.
- Design flexural reinforcement for the strip.
- These two steps, described in the text that follows, are repeated for every load combination. The maximum reinforcement calculated for the top and bottom of the slab within each design strip, along with the corresponding controlling load combination, is obtained and reported.

4.5.1.1 Determine Factored Moments

In the design of flexural reinforcement of concrete slab, the factored moments for each load combination at a particular design strip are obtained by factoring the corresponding moments for different load cases, with the corresponding load factors.

The slab is then designed for the maximum positive and maximum negative factored moments obtained from all of the load combinations. Calculation of bottom reinforcement is based on positive design strip moments. In such cases, the slab may be designed as a rectangular or flanged slab section. Calculation of top reinforcement is based on negative design strip moments. In such cases, the slab may be designed as a rectangular or inverted flanged slab section.
**4.5.1.2 Determine Required Flexural Reinforcement**

In the flexural reinforcement design process, the program calculates both the tension and compression reinforcement. Compression reinforcement is added when the applied design moment exceeds the maximum moment capacity of a singly reinforced section. The user has the option of avoiding compression reinforcement by increasing the effective depth, the width, or the strength of the concrete. Note that the flexural reinforcement strength, $f_y$, is limited to 80 ksi (ACI 9.4), even if the material property is defined using a higher value.

The design procedure is based on the simplified rectangular stress block, as shown in Figure 4-1 (ACI 10.2). Furthermore, it is assumed that the net tensile strain in the reinforcement shall not be less than 0.005 (tension controlled) (ACI 10.3.4) when the concrete in compression reaches its assumed strain limit of 0.003. When the applied moment exceeds the moment capacity at this design condition, the area of compression reinforcement is calculated assuming that the additional moment will be carried by compression reinforcement and additional tension reinforcement.

The design procedure used by ETABS, for both rectangular and flanged sections (L- and T-shaped sections), is summarized in the text that follows. For reinforced concrete design where design ultimate axial compression load does not exceed $0.1f'cA_g$ (ACI 10.3.5), axial force is ignored; hence, all slabs are designed for major direction flexure and shear only. Axial compression greater than $0.1f'cA_g$ and axial tensions are always included in flexural and shear design.

**4.5.1.2.1 Design of uniform thickness slab**

In designing for a factored negative or positive moment, $M_u$ (i.e., designing top or bottom reinforcement), the depth of the compression block is given by $a$ (see Figure 4-1), where,

$$a = d - \sqrt{d^2 - \frac{2|M_u|}{0.85f_c'\phi b}}$$  \hspace{1cm} (ACI 10.2)

and the value of $\phi$ is taken as that for a tension-controlled section, which by default is 0.90 (ACI 9.3.2.1) in the preceding and the following equations.
The maximum depth of the compression zone, $c_{\text{max}}$, is calculated based on the limitation that the tension reinforcement strain shall not be less than $\varepsilon_{\text{min}}$, which is equal to 0.005 for tension controlled behavior (ACI 10.3.4):

$$c_{\text{max}} = \frac{\varepsilon_{\text{max}}}{\varepsilon_{\text{max}} + \varepsilon_{\text{min}}} \cdot d$$  \hspace{1cm} (ACI 10.2.2)

where,

$$\varepsilon_{\text{max}} = 0.003$$  \hspace{1cm} (ACI 10.2.3)

$$\varepsilon_{\text{min}} = 0.005$$  \hspace{1cm} (ACI 10.3.4)

The maximum allowable depth of the rectangular compression block, $a_{\text{max}}$, is given by:

$$a_{\text{max}} = \beta_1 c_{\text{max}}$$  \hspace{1cm} (ACI 10.2.7.1)

where $\beta_1$ is calculated as:

4 - 8 Slab Design
\[ \beta_1 = 0.85 - 0.05 \left( \frac{f'_{c} - 4000}{1000} \right), \quad 0.65 \leq \beta_1 \leq 0.85 \quad \text{(ACI 10.2.7.3)} \]

- If \( a \leq a_{\text{max}} \) (ACI 10.3.4), the area of tension reinforcement is then given by:

\[ A_y = \frac{M_u}{\phi f_y \left( d - \frac{a}{2} \right)} \]

This reinforcement is to be placed at the bottom if \( M_u \) is positive, or at the top if \( M_u \) is negative.

- If \( a > a_{\text{max}} \), compression reinforcement is required (ACI 10.3.5.1) and is calculated as follows:
  - The compressive force developed in the concrete alone is given by:
  \[ C = 0.85 f'_{c} b a_{\text{max}} \quad \text{(ACI 10.2.7.1)} \]
  and the moment resisted by concrete compression and tension reinforcement is:
  \[ M_{uc} = \phi C \left( d - \frac{a_{\text{max}}}{2} \right) \quad \text{(ACI 9.3.2.1)} \]
  - Therefore the moment required to be resisted by compression reinforcement and tension reinforcement is:
  \[ M_{us} = M_u - M_{uc} \]
  - The required compression reinforcement is given by:
  \[ A'_{s} = \frac{M_{us}}{\phi (f'_{s} - 0.85 f'_{c})(d - d')} \], where
  \[ f'_{s} = E_v \varepsilon_{c_{\text{max}}} \left[ \frac{c_{\text{max}} - d'}{c_{\text{max}}} \right] \leq f_y \quad \text{(ACI 10.2.2, 10.2.3, 10.2.4)} \]
The required tension reinforcement for balancing the compression in the concrete is:

\[ A_{s1} = \frac{M_{uc}}{\phi f_y \left[ d - \frac{a_{max}}{2} \right]} \]

and the tension reinforcement for balancing the compression reinforcement is given by:

\[ A_{s2} = \frac{M_{as}}{\phi f_y \left( d - d' \right)} \]

Therefore, the total tension reinforcement is \( A_s = A_{s1} + A_{s2} \), and the total compression reinforcement is \( A'_s \). \( A_s \) is to be placed at the bottom and \( A'_s \) is to be placed at the top if \( M_u \) is positive, and vice versa if \( M_u \) is negative.

### 4.5.1.2.2 Design of nonuniform thickness slab

In designing a nonuniform thickness slab, a simplified stress block, as shown in Figure 4-2, is assumed if the flange is under compression, i.e., if the moment is positive. If the moment is negative, the flange comes under tension, and the flange is ignored. In that case, a simplified stress block similar to that shown in Figure 4-1 is assumed on the compression side.
4.5.1.2.2.1 Flanged Slab Section Under Negative Moment

In designing for a factored negative moment, $M_u$ (i.e., designing top reinforcement), the calculation of the reinforcement area is exactly the same as described previously, i.e., no flanged data is used.

4.5.1.2.2.2 Flanged Slab Section Under Positive Moment

If $M_u > 0$, the depth of the compression block is given by:

$$ a = d - \sqrt{d^2 - \frac{2 M_u}{0.85 f'_c \phi b_f}} $$  \hspace{1cm} (ACI 10.2)

where, the value of $\phi$ is taken as that for a tension-controlled section, which by default is 0.90 (ACI 9.3.2.1) in the preceding and the following equations.

The maximum depth of the compression zone, $c_{\text{max}}$, is calculated based on the limitation that the tension reinforcement strain shall not be less than $\varepsilon_{\text{min}}$, which is equal to 0.005 for tension controlled behavior (ACI 10.3.4):
\[ c_{\text{max}} = \frac{\varepsilon_{\text{c,max}}}{\varepsilon_{\text{c,max}} + \varepsilon_{\text{s,min}}} d \]  

(ACI 10.2.2)

where,

\[ \varepsilon_{\text{c,max}} = 0.003 \]  

(ACI 10.2.3)

\[ \varepsilon_{\text{s,min}} = 0.005 \]  

(ACI 10.3.4)

The maximum allowable depth of the rectangular compression block, \( a_{\text{max}} \), is given by:

\[ a_{\text{max}} = \beta_1 c_{\text{max}} \]  

(ACI 10.2.7.1)

where \( \beta_1 \) is calculated as:

\[ \beta_1 = 0.85 - 0.05 \left( \frac{f'_{\text{c}} - 4000}{1000} \right), \quad 0.65 \leq \beta_1 \leq 0.85 \]  

(ACI 10.2.7.3)

- If \( a \leq h_f \), the subsequent calculations for \( A_s \) are exactly the same as previously defined for the uniform thickness slab design. However, in this case, the width of the slab is taken as \( b_f \). Compression reinforcement is required if \( a > a_{\text{max}} \).

- If \( a > h_f \), the calculation for \( A_s \) has two parts. The first part is for balancing the compressive force from the flange, \( C_f \), and the second part is for balancing the compressive force from the web, \( C_w \), as shown in Figure 4-2. \( C_f \) is given by:

\[ C_f = 0.85 f'_{\text{c}} \left( b_f - b_w \right) \min(h_f, a_{\text{max}}) \]  

(ACI 10.2.7.1)

Therefore, \( A_s = \frac{C_f}{f_y} \) and the portion of \( M_u \) that is resisted by the flange is given by:

\[ M_{u,f} = \phi C_f \left( d - \frac{\min(h_f, a_{\text{max}})}{2} \right) \]  

(ACI 9.3.2.1)

Again, the value for \( \phi \) is 0.90 by default. Therefore, the balance of the moment, \( M_{u,w} \), to be carried by the web is:
The web is a rectangular section with dimensions $b_w$ and $d$, for which the design depth of the compression block is recalculated as:

$$a_1 = d - \sqrt{d^2 - \frac{2M_{uw}}{0.85f'_c \phi b_w}}$$

(ACI 10.2)

- If $a_1 \leq a_{max}$ (ACI 10.3.4), the area of tension reinforcement is then given by:

$$A_{s2} = \frac{M_{uw}}{\phi f_y \left(d - \frac{a_1}{2}\right)}$$

and

$$A_s = A_{s1} + A_{s2}$$

This reinforcement is to be placed at the bottom of the flanged slab.

- If $a_1 > a_{max}$, compression reinforcement is required (ACI 10.3.5.1) and is calculated as follows:

The compressive force in the web concrete alone is given by:

$$C_w = 0.85f'_c b_w a_{max}$$

(ACI 10.2.7.1)

Therefore the moment resisted by the concrete web and tension reinforcement is:

$$M_{wc} = C_w \left(d - \frac{a_{max}}{2}\right) \phi$$

and the moment resisted by compression and tension reinforcement is:

$$M_{us} = M_{uw} - M_{wc}$$

Therefore, the compression reinforcement is computed as:

$$A'_s = \frac{M_{us}}{(f'_s - 0.85f'_c)(d - d') \phi},$$

where
\[ f'_s = E_s e_{c_{\text{max}}} \left( \frac{c_{\text{max}} - d'}{c_{\text{max}}} \right) \leq f_y \] (ACI 10.2.2, 10.2.3, 10.2.4)

The tension reinforcement for balancing compression in the web concrete is:

\[ A_{s2} = \frac{M_{hc}}{f_y \left( d - \frac{a_{\text{max}}}{2} \right) \phi} \]

and the tension reinforcement for balancing the compression reinforcement is:

\[ A_{s3} = \frac{M_{dc}}{f_y \left( d - d' \right) \phi} \]

The total tension reinforcement is \( A_s = A_{s1} + A_{s2} + A_{s3} \), and the total compression reinforcement is \( A'_s \). \( A_s \) is to be placed at the bottom and \( A'_s \) is to be placed at the top.

### 4.5.1.2.3 Minimum and Maximum Reinforcement

The minimum flexural tension reinforcement required for each direction of a slab is given by the following limits (ACI 7.12.2):

\[ A_{s,\text{min}} = 0.0020 \frac{bh}{f_y} \text{ for } f_y = 40 \text{ ksi or 50 ksi} \] (ACI 7.12.2.1(a))

\[ A_{s,\text{min}} = 0.0018 \frac{bh}{f_y} \text{ for } f_y = 60 \text{ ksi} \] (ACI 7.12.2.1(b))

\[ A_{s,\text{min}} = \frac{0.0018 \times 60000}{f_y} \text{ for } f_y > 60 \text{ ksi} \] (ACI 7.12.2.1(c))

In addition, an upper limit on both the tension reinforcement and compression reinforcement has been imposed to be 0.04 times the gross cross-sectional area.

### 4.5.2 Design Slab Shear Reinforcement

The shear reinforcement is designed for each load combination at each station along the design strip. In designing the shear reinforcement for a particular strip,
for a particular load combination, at a particular station due to the slab major shear, the following steps are involved:

- Determine the factored shear force, $V_u$.
- Determine the shear force, $V_c$, that can be resisted by the concrete.
- Determine the shear reinforcement required to carry the balance.

The following three sections describe in detail the algorithms associated with these steps.

4.5.2.1 Determine Factored Shear Force

In the design of the slab shear reinforcement, the shear forces for each load combination at a particular design strip station are obtained by factoring the corresponding shear forces for different load cases, with the corresponding load combination factors.

4.5.2.2 Determine Concrete Shear Capacity

The shear force carried by the concrete, $V_c$, is calculated as:

$$V_c = 2\lambda \sqrt{f_c' b_u d}$$  \hspace{1cm} (ACI 11.2.1.2, 11.2.1.2, 11.2.2.3)

A limit is imposed on the value of $f_c'$ as $f_c' \leq 100$  \hspace{1cm} (ACI 11.1.2)

The value of $\lambda$ should be specified in the material property definition.

4.5.2.3 Determine Required Shear Reinforcement

The shear force is limited to a maximum of:

$$V_{\text{max}} = V_c + \left(8\sqrt{f_c'}\right) b_u d$$  \hspace{1cm} (ACI 11.4.7.9)

Given $V_u$, $V_c$, and $V_{\text{max}}$, the required shear reinforcement is calculated as follows where, $\phi$, the strength reduction factor, is 0.75 (ACI 9.3.2.3). The flexural reinforcement strength, $f_{fr}$, is limited to 60 ksi (ACI 11.5.2) even if the material property is defined with a higher value.
If \( V_u \leq \phi V_c \),
\[
\frac{A_v}{s} = 0 \quad \text{(ACI 11.5.6.1)}
\]

If \( \phi V_c < V_u < \phi V_{\text{max}} \),
\[
\frac{A_v}{s} = \frac{(V_u - \phi V_c)}{\phi f_{\text{yt}} d} \quad \text{(ACI 11.4.7.1, 11.4.7.2)}
\]

If \( V_u > \phi V_{\text{max}} \), a failure condition is declared. \( \text{(ACI 11.4.7.9)} \)

If \( V_u \) exceeds the maximum permitted value of \( \phi V_{\text{max}} \), the concrete section should be increased in size (ACI 11.4.7.9).

The minimum shear reinforcement given by ACI 11.4.6.3 is not enforced (ACI 11.4.6.1).
\[
\frac{A_v}{s} \geq \max \left( \frac{0.75 \lambda \sqrt{f'_c}}{f_{\text{yt}} b_w}, \frac{50 b_w}{f_{\text{yt}}} \right) \quad \text{(ACI 11.4.6.3)}
\]

The maximum of all of the calculated \( A_v/s \) values obtained from each load combination is reported along with the controlling shear force and associated load combination.

The slab shear reinforcement requirements considered by the program are based purely on shear strength considerations. Any minimum stirrup requirements to satisfy spacing and volumetric considerations must be investigated independently of the program by the user.

**4.5.3 Check for Punching Shear**

The algorithm for checking punching shear is detailed in the section entitled “Slab Punching Shear Check” in the Chapter 1. Only the code-specific items are described in the following sections.
4.5.3.1 Critical Section for Punching Shear

The punching shear is checked on a critical section at a distance of $d/2$ from the face of the support (ACI 11.11.1.2). For rectangular columns and concentrated loads, the critical area is taken as a rectangular area with the sides parallel to the sides of the columns or the point loads (ACI 11.11.1.3). Figure 4-3 shows the auto punching perimeters considered by ETABS for the various column shapes. The column location (i.e., interior, edge, corner) and the punching perimeter may be overwritten using the Punching Check Overwrites.

![Figure 4-3 Punching Shear Perimeters](image)

4.5.3.2 Transfer of Unbalanced Moment

The fraction of unbalanced moment transferred by flexure is taken to be $\gamma_f M_u$ and the fraction of unbalanced moment transferred by eccentricity of shear is taken to be $\gamma_v M_u$.

$$\gamma_f = \frac{1}{1 + (2/3)\sqrt{b_1/b_2}} \quad \text{(ACI 13.5.3.2)}$$
ETABS Reinforced Concrete Design

\[ \gamma_v = 1 - \gamma_f \]  
(ACI 13.5.3.1)

For flat plates, \( \gamma_v \) is determined from the following equations taken from ACI 421.2R-07 Seismic Design of Punching Shear Reinforcement in Flat Plates [ACI 2007].

For interior columns,

\[ \gamma_{vx} = 1 - \frac{1}{1 + (2/3) \sqrt{l_y/l_x}} \]  
(ACI 421.2 C-11)

\[ \gamma_{vy} = 1 - \frac{1}{1 + (2/3) \sqrt{l_x/l_y}} \]  
(ACI 421.2 C-12)

For edge columns,

\[ \gamma_{vx} = \text{same as for interior columns} \]  
(ACI 421.2 C-13)

\[ \gamma_{vy} = 1 - \frac{1}{1 + (2/3) \sqrt{l_x/l_y} - 0.2} \]  
(ACI 421.2 C-14)

\[ \gamma_{vy} = 0 \text{ when } l_x/l_y \leq 0.2 \]

For corner columns,

\[ \gamma_{vx} = 0.4 \]  
(ACI 421.2 C-15)

\[ \gamma_{vy} = \text{same as for edge columns} \]  
(ACI 421.2 C-16)

**NOTE:** Program uses ACI 421.4-12 and ACI 421.4-15 equations in lieu of ACI 421.2 C-14 and ACI 421.2 C-16 which are currently NOT enforced.

where \( b_1 \) is the width of the critical section measured in the direction of the span and \( b_2 \) is the width of the critical section measured in the direction perpendicular to the span. The values \( l_x \) and \( l_y \) are the projections of the shear-critical section onto its principal axes, \( x \) and \( y \), respectively.
4.5.3.3 Determine Concrete Capacity

The concrete punching shear stress capacity is taken as the minimum of the following three limits:

\[
v_c = \min \left\{ \phi \left( 2 + \frac{4}{\beta_c} \right) \lambda \sqrt{f'_c} \right\}
\]

(ACI 11.1.2.1)

\[
v_c = \min \left\{ \phi \left( 2 + \frac{x_{sd}}{b_o} \right) \lambda \sqrt{f'_c} \right\}
\]

(ACI 11.1.2.1)

\[
v_c = \phi 4 \lambda \sqrt{f'_c}
\]

where, \(\beta_c\) is the ratio of the maximum to the minimum dimensions of the critical section, \(b_o\) is the perimeter of the critical section, and \(x_s\) is a scale factor based on the location of the critical section.

\[\alpha_s = \begin{cases} 40 & \text{for interior columns,} \\ 30 & \text{for edge columns,} \\ 20 & \text{for corner columns.} \end{cases}\]

(ACI 11.1.2.1)

A limit is imposed on the value of \(\sqrt{f'_c}\) as:

\[\sqrt{f'_c} \leq 100\]

(ACI 11.1.2)

4.5.3.4 Computation of Maximum Shear Stress

Given the punching shear force and the fractions of moments transferred by eccentricity of shear about the two axes, the shear stress is computed assuming linear variation along the perimeter of the critical section.

\[
v_u = \frac{V_u}{b_o d} + \frac{\gamma M_{u2} - V_u (y_3 - y_1)}{I_{22} I_{33} - I_{23}^2} \left[ I_{33} (y_4 - y_3) - I_{23} (x_4 - x_3) \right] - \frac{\gamma M_{u3} - V_u (x_3 - x_1)}{I_{22} I_{33} - I_{23}^2} \left[ I_{22} (x_4 - x_3) - I_{23} (y_4 - y_3) \right]
\]

Eq. 1

\[
\gamma = \phi \left( 2 + \frac{x_{sd}}{b_o} \right) \lambda \sqrt{f'_c}
\]
\[ I_{23} = \sum_{sides=1}^{n} T_{23}, \]  where "sides" refers to the sides of the critical section for punching shear  

\[ I_{33} = \sum_{sides=1}^{n} T_{33}, \]  where "sides" refers to the sides of the critical section for punching shear  

The equations for \( T_{22}, T_{33}, \) and \( T_{23} \) are different depending on whether the side of the critical section for punching shear being considered is parallel to the 4-axis or parallel to the 3-axis. Refer to Figure 4-4.

\[ T_{22} = Ld(y_2 - y_3)^2, \text{ for the side of the critical section parallel to the 4-axis} \]  

\[ T_{22} = \frac{Ld^3}{12} + \frac{dl^3}{12} + Ld(y_2 - y_3)^2, \text{ for the side of the critical section parallel to the 3-axis} \]  

\[ T_{33} = \frac{Ld^3}{12} + \frac{dl^3}{12} + Ld(x_2 - x_3)^2, \text{ for the side of the critical section parallel to the 4-axis} \]  

\[ T_{33} = Ld(x_2 - x_3)^2, \text{ for the side of the critical section parallel to the 3-axis} \]
Chapter 4 - Design for ACI 318-08

Figure 4-4 Shear Stress Calculations at Critical Sections

$$\overline{T}_{23} = Ld(x_2 - x_3)(y_2 - y_3)$$, for side of critical section parallel to 4-axis or 3-axis

Eq. 7

NOTE: $\overline{T}_{23}$ is explicitly set to zero for corner condition.

where,

- $b_0$ = Perimeter of the critical section for punching shear
- $d$ = Effective depth at the critical section for punching shear based on the average of $d$ for 2 direction and $d$ for 3 direction
- $I_{22}$ = Moment of inertia of the critical section for punching shear about an axis that is parallel to the local 4-axis
\[ I_{33} = \text{Moment of inertia of the critical section for punching shear about an axis that is parallel to the local 3-axis} \]

\[ I_{23} = \text{Product of the inertia of the critical section for punching shear with respect to the 2 and 3 planes} \]

\[ L = \text{Length of the side of the critical section for punching shear currently being considered} \]

\[ M_{U2} = \text{Moment about the line parallel to the 4-axis at the center of the column (positive in accordance with the right-hand rule)} \]

\[ M_{U3} = \text{Moment about the line parallel to the 3-axis at the center of the column (positive in accordance with the right-hand rule)} \]

\[ v_U = \text{Punching shear stress} \]

\[ V_U = \text{Shear at the center of the column (positive upward)} \]

\[ x_1, y_1 = \text{Coordinates of the column centroid} \]

\[ x_2, y_2 = \text{Coordinates of the center of one side of the critical section for punching shear} \]

\[ x_3, y_3 = \text{Coordinates of the centroid of the critical section for punching shear} \]

\[ x_4, y_4 = \text{Coordinates of the location where stress is being calculated} \]

\[ \gamma_{V2} = \text{Percent of } M_{U2} \text{ resisted by shear} \]

\[ \gamma_{V3} = \text{Percent of } M_{U3} \text{ resisted by shear} \]

**4.5.3.5 Determine Capacity Ratio**

Given the punching shear force and the fractions of moments transferred by eccentricity of shear about the two axes, the shear stress is computed assuming linear variation along the perimeter of the critical section. The ratio of the maximum shear stress and the concrete punching shear stress capacity is reported as the punching shear capacity ratio by ETABS. If this ratio exceeds 1.0, punching shear reinforcement is designed as described in the following section.
Design Punching Shear Reinforcement

The use of shear studs as shear reinforcement in slabs is permitted, provided that the effective depth of the slab is greater than or equal to 6 inches, and not less than 16 times the shear reinforcement bar diameter (ACI 11.11.3). If the slab thickness does not meet these requirements, the punching shear reinforcement is not designed and the slab thickness should be increased by the user.

The algorithm for designing the required punching shear reinforcement is used when the punching shear capacity ratio exceeds unity. The Critical Section for Punching Shear and Transfer of Unbalanced Moment as described in the earlier sections remain unchanged. The design of punching shear reinforcement is described in the subsections that follow.

4.5.4.1 Determine Concrete Shear Capacity

The concrete punching shear stress capacity of a section with punching shear reinforcement is limited to:

\[ \nu_c \leq \phi 2 \lambda \sqrt{f'_c} \]  
for shear links \hspace{1cm} (ACI 11.11.3.1)

\[ \nu_c \leq \phi 3 \lambda \sqrt{f'_c} \]  
for shear studs \hspace{1cm} (ACI 11.11.5.1)

4.5.4.2 Determine Required Shear Reinforcement

The shear force is limited to a maximum of:

\[ V_{\text{max}} = 6 \sqrt{f'_c b_d} \]  
for shear links \hspace{1cm} (ACI 11.11.3.2)

\[ V_{\text{max}} = 8 \sqrt{f'_c b_d} \]  
for shear studs \hspace{1cm} (ACI 11.11.5.1)

Given \( V_u, V_c, \) and \( V_{\text{max}}, \) the required shear reinforcement is calculated as follows, where, \( \phi, \) the strength reduction factor, is 0.75 (ACI 9.3.2.3).

\[ \frac{A_s}{s} = \left( \frac{V_u - \phi V_c}{\phi f_{yd} d} \right) \]  
\hspace{1cm} (ACI 11.4.7.1, 11.4.7.2)
\[ \frac{A_v}{s} \geq \frac{2\sqrt{f'c b_o}}{f_y} \] for shear studs \hspace{1cm} (ACI 11.11.5.1)

- If \( V_u > \phi V_{\text{max}} \), a failure condition is declared. \hspace{1cm} (ACI 11.11.3.2)
- If \( V_o \) exceeds the maximum permitted value of \( \phi V_{\text{max}} \), the concrete section should be increased in size.

### 4.5.4.3 Determine Reinforcement Arrangement

Punching shear reinforcement in the vicinity of rectangular columns should be arranged on peripheral lines, i.e., lines running parallel to and at constant distances from the sides of the column. Figure 4-6 shows a typical arrangement of shear reinforcement in the vicinity of a rectangular interior, edge, and corner column.

**Figure 4-6 Typical arrangement of shear studs and critical sections outside shear-reinforced zone**

The distance between the column face and the first line of shear reinforcement shall not exceed \( d/2 \) (ACI R11.3.3, 11.11.5.2). The spacing between adjacent shear reinforcement in the first line (perimeter) of shear reinforcement shall not exceed \( 2d \) measured in a direction parallel to the column face (ACI 11.11.3.3).

Punching shear reinforcement is most effective near column corners where there are concentrations of shear stress. Therefore, the minimum number of lines of
shear reinforcement is 4, 6, and 8, for corner, edge, and interior columns respectively.

4.5.4.4 Determine Reinforcement Diameter, Height, and Spacing

The punching shear reinforcement is most effective when the anchorage is close to the top and bottom surfaces of the slab. The cover of anchors should not be less than the minimum cover specified in ACI 7.7 plus half of the diameter of the flexural reinforcement.

Punching shear reinforcement in the form of shear studs is generally available in 3/8-, 1/4-, 5/8-, and 3/4-inch diameters.

When specifying shear studs, the distance, \( s_o \), between the column face and the first peripheral line of shear studs should not be smaller than 0.5\( d \). The spacing between adjacent shear studs, \( g \), at the first peripheral line of studs shall not exceed 2\( d \), and in the case of studs in a radial pattern, the angle between adjacent stud rails shall not exceed 60 degrees. The limits of \( s_o \) and the spacing, \( s \), between the peripheral lines are specified as:

\[
s_o \leq 0.5d \\
 s \leq \begin{cases} 
 0.75d & \text{for } \nu_u \leq 6\phi\lambda\sqrt{f'_c} \\
 0.50d & \text{for } \nu_u > 6\phi\lambda\sqrt{f'_c}
\end{cases} \\
g \leq 2d
\]

The limits of \( s_o \) and the spacing, \( s \), between for the links are specified as:

\[
s_o \leq 0.5d \\
 s \leq 0.50d
\]
Chapter 05
Design for AS 3600-09

This chapter describes in detail the various aspects of the concrete design procedure that is used by ETABS when the Australian code AS 3600-2009 [AS 2009] is selected. Various notations used in this chapter are listed in Table 5-1. For referencing to the pertinent sections of the AS code in this chapter, a prefix “AS” followed by the section number is used.

The design is based on user-specified load combinations. The program provides a set of default load combinations that should satisfy the requirements for the design of most building type structures.

English as well as SI and MKS metric units can be used for input. The code is based on Newton-millimeter-second units. For simplicity, all equations and descriptions presented in this chapter correspond to Newton-millimeter-second units unless otherwise noted.

5.2 Design Load Combinations

The design load combinations are the various combinations of the load cases for which the structure needs to be designed. For AS 3600-09, if a structure is subjected to dead (D), live (L), pattern live (PL), snow (S), wind (W), and earthquake (E) loads, and considering that wind and earthquake forces are reversible, the following load combinations may need to be defined (AS 2.4.2):

- $1.35D$ (AS/NZS 1170.0-02, 4.2.2(a))
- $1.2D + 1.5L$ (AS/NZS 1170.0-02, 4.2.2(b))
- $1.2D + 1.5(0.75 PL)$ (AS/NZS 1170.0-02, 4.2.2(b))
- $1.2D + 0.4L + 1.0S$ (AS/NZS 1170.0-02, 4.2.2(g))
- $0.9D \pm 1.0W$ (AS/NZS 1170.0-02, 4.2.2(e))
- $1.2D \pm 1.0W$ (AS/NZS 1170.0-02, 4.2.2(d))
- $1.2D + 0.4L \pm 1.0W$ (AS/NZS 1170.0-02, 4.2.2(d))
- $1.0D \pm 1.0E$ (AS/NZS 1170.0-02, 4.2.2(f))
- $1.0D + 0.4L \pm 1.0E$ (AS/NZS 1170.0-02, 4.2.2(f))

Note that the 0.4 factor on the live load in three of the combinations is not valid for live load representing storage areas. These are also the default design load combinations in ETABS whenever the AS 3600-2009 code is used. If roof live load is treated separately or other types of loads are present, other appropriate load combinations should be used.
5.3 Limits on Material Strength

The upper and lower limits of $f'_{c}$ are 100 MPa and 20 MPa, respectively, for all framing types (AS 3.1.1.1(b)).

\[ f'_{c} \leq 100 \text{ MPa} \quad \text{(AS 3.1.1.1)} \]

\[ f'_{c} \geq 20 \text{ MPa} \quad \text{(AS 3.1.1.1)} \]

The upper limit of $f_{sy}$ is 500 MPa for all frames (AS 3.2.1, Table 3.2.1).

The code allows use of $f'_{c}$ and $f_{sy}$ beyond the given limits, provided special care is taken regarding the detailing and ductility (AS 3.1.1, 3.2.1, 17.2.1.1).

ETABS enforces the upper material strength limits for flexure and shear design of slabs. The input material strengths are taken as the upper limits if they are defined in the material properties as being greater than the limits. The user is responsible for ensuring that the minimum strength is satisfied.

5.4 Strength Reduction Factors

The strength reduction factor, $\phi$, is defined as given in AS 2.2.2(ii), Table 2.2.2:

For members with Class N reinforcement only

\[ \phi = 0.80 \text{ for flexure (tension controlled)} \quad \text{(Table 2.2.2(b))} \]

\[ \phi = 0.60 \text{ for flexure (compression controlled)} \quad \text{(Table 2.2.2(b))} \]

For members with Class L reinforcement

\[ \phi = 0.64 \text{ for flexure (tension controlled)} \quad \text{(Table 2.2.2(b))} \]

\[ \phi = 0.60 \text{ for flexure (compression controlled)} \quad \text{(Table 2.2.2(b))} \]

\[ \phi = 0.70 \text{ for shear and torsion} \quad \text{(Table 2.2.2(b))} \]

These values can be overwritten; however, caution is advised.
5.5 Slab Design

ETABS slab design procedure involves defining sets of strips in two mutually perpendicular directions. The locations of the strips are usually governed by the locations of the slab supports. The axial force, moments and shears for a particular strip are recovered from the analysis (on the basis of the Wood-Armer technique), and a flexural design is carried out based on the ultimate strength design method.

The slab design procedure involves the following steps:

- Design flexural reinforcement
- Design shear reinforcement
- Punching check

5.5.1 Design Flexural Reinforcement

For slabs, ETABS uses either design strips or the finite element based design to calculate the slab flexural reinforcement in accordance with the selected design code. For simplicity, only strip-by-strip design is documented in the proceeding sections.

The design of the slab reinforcement for a particular strip is carried out at specific locations along the length of the strip. These locations correspond to the element boundaries. Controlling reinforcement is computed on either side of those element boundaries. The slab flexural design procedure for each load combination involves the following:

- Determine factored axial loads and moments for each slab strip.
- Design flexural reinforcement for the strip.
- These two steps, described in the text that follows, are repeated for every load combination. The maximum reinforcement calculated for the top and bottom of the slab within each design strip, along with the corresponding controlling load combination, is obtained and reported.
5.5.1.1 Determine Factored Moments

In the design of flexural reinforcement of concrete slab, the factored moments for each load combination at a particular design strip are obtained by factoring the corresponding moments for different load cases, with the corresponding load factors.

The slab is then designed for the maximum positive and maximum negative factored moments obtained from all of the load combinations. Calculation of bottom reinforcement is based on positive design strip moments. In such cases, the slab may be designed as a rectangular or flanged slab section. Calculation of top reinforcement is based on negative design strip moments. In such cases, the slab may be designed as a rectangular or inverted flanged slab section.

5.5.1.2 Determine Required Flexural Reinforcement

In the flexural reinforcement design process, the program calculates both the tension and compression reinforcement. Compression reinforcement is added when the applied design moment exceeds the maximum moment capacity of a singly reinforced section. The user has the option of avoiding compression reinforcement by increasing the effective depth, the width, or the strength of the concrete. Note that the flexural reinforcement strength, \( f_y \), is limited to 500MPa (AS 3.2.1), even if the material property is defined using a higher value.

The design procedure is based on the simplified rectangular stress block, as shown in Figure 5-1 (AS 8.1.2).

The following assumptions apply to the stress block used to compute the flexural bending capacity of rectangular sections (AS 8.1.2):

- The maximum strain in the extreme compression fiber is taken as 0.003 (AS 8.1.3(a)).

- A uniform compressive stress of \( a_2 f' \) acts on an area (AS 8.1.3(b)) bounded by:
  - The edges of the cross-sections.
  - A line parallel to the neutral axis at the strength limit under the loading concerned, and located at a distance \( y_{cd} \) from the extreme compression fiber.
The maximum allowable depth of the rectangular compression block, $a_{\text{max}}$, is given by

\[ a_{\text{max}} = \gamma k_u d \]  
where,

\[ \alpha_2 = 1.0 - 0.003 f'_c \]  
where, $0.67 \leq \alpha_2 \leq 0.85$ (AS 8.1.3(1))

\[ \gamma = 1.05 - 0.007 f'_c \]  
where, $0.67 \leq \gamma \leq 0.85$ (AS 8.1.3(2))

\[ k_u = 0.36 \]  
(AS 8.1.5)

The design procedure used by ETABS for both rectangular and flanged sections (L- and T-shaped sections) is summarized in the following subsections. It is assumed that the design ultimate axial force does not exceed ($A_{\text{uc}} f_{\text{sy}} > 0.15 N^*$) (AS 10.7.1a); hence, all slabs are designed for major direction flexure, shear, and torsion only.

### 5.5.1.3 Design of uniform thickness slab

In designing for a factored negative or positive moment, $M^*$ (i.e., designing top or bottom reinforcement), the depth of the compression block is given by $a$ (see Figure 5-1), where,

\[ a = d - \sqrt{d^2 - \frac{2 |M^*|}{\alpha_2 f'_c \phi b}} \]  
(AS 8.1.3)
where, the value of $\phi$ is taken as that for a tension controlled section ($k_u \leq 0.36$), which by default is 0.80 (AS 2.2.2) in the preceding and following equations. The selection of Reinforcement Class can be made using the Design Preferences.

- If $a \leq a_{\text{max}}$, the area of tension reinforcement is then given by:

$$A_{\text{t}} = \frac{M^*}{\phi f_{y} \left( d - \frac{a}{2} \right)}$$

This reinforcement is to be placed at the bottom if $M^*$ is positive, or at the top if $M^*$ is negative.

- If $a > a_{\text{max}}$, i.e., $k_u > 0.36$, compression reinforcement is required (AS 8.1.5) and is calculated as follows:

The compressive force developed in the concrete alone is given by:
\[ C = \alpha_2 f^* c b_{\text{max}} \]  

(AS 8.1.3)

and the moment resisted by concrete compression and tension reinforcement is:

\[ M_{\text{wc}} = C \left( d - \frac{a_{\text{max}}}{2} \right) \phi \]

Therefore, the moment required to be resisted by compression reinforcement and tension reinforcement is:

\[ M_{\text{us}} = M^* - M_{\text{wc}} \]

The required compression reinforcement is given by:

\[ A_{\text{sc}} = \frac{M_{\text{us}}}{(f^* - \alpha_2 f^*)(d - d')\phi}, \text{ where} \]

\[ f^* = 0.003E_{\text{st}} \left[ \frac{c - d'}{c} \right] \leq f_{\text{sy}} \]  

(AS 8.1.2.1, 3.2.2)

The required tension reinforcement for balancing the compression in the concrete is:

\[ A_{s1} = \frac{M_{\text{wc}}}{f_{\text{sy}} \left( d - \frac{a_{\text{max}}}{2} \right) \phi} \]

and the tension reinforcement for balancing the compression reinforcement is given by:

\[ A_{s2} = \frac{M_{\text{us}}}{f_{\text{sy}} (d - d') \phi} \]

Therefore, the total tension reinforcement is \( A_{sT} = A_{s1} + A_{s2} \), and the total compression reinforcement is \( A_{sc} \). \( A_{sT} \) is to be placed at the bottom and \( A_{sc} \) is to be placed at the top if \( M^* \) is positive, and vice versa if \( M^* \) is negative.
5.5.1.4 Design of nonuniform thickness slab

In designing a nonuniform thickness slab, a simplified stress block, as shown in Figure 5-2, is assumed if the flange is under compression, i.e., if the moment is positive. If the moment is negative, the flange comes under tension, and the flange is ignored. In that case, a simplified stress block similar to that shown in Figure 5-1 is assumed on the compression side (AS 8.1.5).

![Figure 5-2 T- Nonuniform Thickness Slab Design](image)

5.5.1.5 Flanged Slab Section Under Negative Moment

In designing for a factored negative moment, $M^*$ (i.e., designing top reinforcement), the calculation of the reinforcement is exactly the same as above, i.e., no flanged data is used.

5.5.1.6 Flanged Slab Section Under Positive Moment

If $M^* > 0$, the depth of the compression block is given by:

$$a = d - \sqrt{d^2 - \frac{2M^*}{\alpha_2 f'_c \phi b_f}}$$

where, the value of $\phi$ is taken as that for $k_u \leq 0.36$, which is 0.80 by default (AS 2.2.2) in the preceding and the following equations.
The maximum allowable depth of the rectangular compression block, \( a_{\text{max}} \), is given by:

\[
a_{\text{max}} = \gamma k_u d \quad \text{where, } k_u = 0.36
\]

(AS 8.1.5)

- If \( a \leq D_s \), the subsequent calculations for \( A_{\text{st}} \) are exactly the same as previously defined for the uniform thickness slab design. However, in that case, the width of the sklab is taken as \( b_f \). Compression reinforcement is required when \( a > a_{\text{max}} \).

- If \( a > D_s \), the calculation for \( A_{\text{st}} \) has two parts. The first part is for balancing the compressive force from the flange, \( C_f \), and the second part is for balancing the compressive force from the web, \( C_w \), as shown in Figure 5-2. \( C_f \) is given by:

\[
C_f = \alpha \frac{f'_c}{f_{\text{sy}}} \left( b_f - b_w \right) \times \min \left( D_s, a_{\text{max}} \right)
\]

(AS 8.1.3(b))

Therefore, \( A_{\text{st}} = \frac{C_f}{f_{\text{sy}}} \) and the portion of \( M^* \) that is resisted by the flange is given by:

\[
M_{\text{uf}} = \phi C_f \left( d - \frac{\min \left( D_s, a_{\text{max}} \right)}{2} \right)
\]

Therefore, the balance of the moment \( M^* \) to be carried by the web is:

\[
M_{\text{uw}} = M^* - M_{\text{uf}}
\]

The web is a rectangular section of dimensions \( b_w \) and \( d \), for which the design depth of the compression block is recalculated as:

\[
a_1 = d = \sqrt{d^2 - \frac{2M_{\text{uw}}}{\alpha \frac{f'_c}{f_{\text{sy}}} \phi b_w}}
\]

- If \( a_1 \leq a_{\text{max}} \), the area of tension reinforcement is then given by:
\[ A_{s2} = \frac{M_{uw}}{\phi f_{sy} \left( d - \frac{a_1}{2} \right)}, \text{ and} \]

\[ A_{s1} = A_{s1} + A_{s2} \]

This reinforcement is to be placed at the bottom of the flanged slab.

- If \( a_1 > a_{\text{max}} \), compression reinforcement is required and is calculated as follows:

The compression force in the web concrete alone is given by:

\[ C_w = \alpha_2 f' c b_w a_{\text{max}} \quad \text{(AS 8.1.3)} \]

Therefore the moment resisted by the concrete web and tension reinforcement is:

\[ M_{wc} = C_w \left( d - \frac{a_{\text{max}}}{2} \right) \phi \]

and the moment resisted by compression and tension reinforcement is:

\[ M_{w} = M_{uw} - M_{wc} \]

Therefore, the compression reinforcement is computed as:

\[ A_{wc} = \frac{M_{w}}{(f' c - \alpha_2 f' c')(d - d') \phi}, \text{ where} \]

\[ f' c = 0.003 E_s \left[ \frac{c_{\text{max}} - d'}{c_{\text{max}}} \right] \leq f_{sy} \quad \text{(AS 8.1.2.1, 3.2.2)} \]

The tension reinforcement for balancing compression in the web concrete is:

\[ A_{s2} = \frac{M_{wc}}{f_{sy} \left( d - \frac{a_{\text{max}}}{2} \right) \phi} \]
and the tension reinforcement for balancing the compression reinforcement is:

\[ A_{s3} = \frac{M_{us}}{f_{sy} (d - d') \phi} \]

The total tensile reinforcement is \( A_{st} = A_{s1} + A_{s2} + A_{s3} \), and the total compression reinforcement is \( A_{sc} \). \( A_{st} \) is to be placed at the bottom and \( A_{sc} \) is to be placed at the top.

### 5.5.1.7 Minimum and Maximum Reinforcement

The minimum flexural tensile reinforcement required for each direction of a slab is given by the following limits (AS 9.1.1):

\[ A_s = 0.24 \left( \frac{h}{d} \right)^2 \frac{f'_{ct,f}}{f_{sy,f}} bh \quad \text{for flat slabs} \quad \text{(AS 9.1.1(a))} \]

\[ A_s = 0.19 \left( \frac{h}{d} \right)^2 \frac{f'_{ct,f}}{f_{sy,f}} bh \]

\[ \text{for slabs supported by beams/walls and slab footings.} \quad \text{(AS 9.1.1(b))} \]

In addition, an upper limit on both the tension reinforcement and compression reinforcement has been imposed to be 0.04 times the gross cross-sectional area.

### 5.5.2 Design Slab Shear Reinforcement

The shear reinforcement is designed for each load combination at each station along the design strip. In designing the shear reinforcement for a particular strip, for a particular load combination, at a particular station due to the slab major shear, the following steps are involved:

- Determine the factored shear force, \( V^* \).
- Determine the shear force, \( V_{uc} \), that can be resisted by the concrete.
- Determine the shear reinforcement required to carry the balance.
The following three sections describe in detail the algorithms associated with these steps.

5.5.2.1 Determine Shear Force

In the design of the slab shear reinforcement, the shear forces for each load combination at a particular design strip station are obtained by factoring the corresponding shear forces for different load cases, with the corresponding load combination factors.

5.5.2.2 Determine Concrete Shear Capacity

The shear force carried by the concrete, $V_{uc}$, is calculated as:

$$V_{uc} = \beta_1 \beta_2 \beta_3 b_d d_o f'_{cv} \left[ \frac{A_{u}}{b_d d_o} \right]^{1/3}$$  \hspace{1cm} (AS 8.2.7.1)

where,

$$f'_{cv} = \left( f'_{c} \right)^{1/3} \leq 4 \text{MPa}$$  \hspace{1cm} (AS 8.2.7.1)

$$\beta_1 = 1.1 \left( 1.6 - \frac{d_o}{1000} \right) \geq 1.1$$  \hspace{1cm} (AS 8.2.7.1)

$$\beta_2 = 1$$  \hspace{1cm} (AS 8.2.7.1)

$$= 1 - \left( \frac{N^*}{3.5A_g} \right) \geq 0$$ for members subject to significant axial tension, or

$$= 1 + \left( \frac{N^*}{14A_g} \right)$$ for members subject to significant axial compression.

$$\beta_3 = 1$$

5.5.2.3 Determine Required Shear Reinforcement

The shear force is limited to:
Given $V^*$, $V_{uc}$, and $V_{u,max}$, the required shear reinforcement is calculated as follows, where, $\phi$, the strength reduction factor, is 0.75 by default (AS 2.2.2).

- If $V^* \leq \phi V_{uc}/2$,
  \[
  \frac{A_{sv}}{s} = 0, \text{ if } D \leq 750 \text{ mm; otherwise } A_{sv,\min} \text{ shall be provided.} \quad \text{(AS 8.2.5)}
  \]

- If $(\phi V_{uc}/2) < V^* \leq \phi V_{u,\min}$,
  \[
  \frac{A_{sv}}{s} = 0, \text{ if } D < b_w/2 \text{ or } 250 \text{ mm, whichever is greater (AS 8.2.5(c)(i)); otherwise } A_{sv,\min} \text{ shall be provided.}
  \]

- If $\phi V_{u,\min} < V^* \leq \phi V_{u,\max}$,
  \[
  \frac{A_{sv}}{s} = \frac{V^* - \phi V_{uc}}{\phi f_{sy,f} d_o \cot \theta_v}, \quad \text{(AS 8.2.10)}
  \]
  and greater than $A_{sv,\min}$, defined as:
  \[
  \frac{A_{sv,\min}}{s} = \left(0.35 \frac{b_w}{f_{sy,f}}\right) \quad \text{(AS 8.2.8)}
  \]

  $\theta_v$ = the angle between the axis of the concrete compression strut and the longitudinal axis of the member, which varies linearly from 30 degrees when $V^* = \phi V_{u,\min}$ to 45 degrees when $V^* = \phi V_{u,\max}$.

- If $V^* > \phi V_{u,\max}$, a failure condition is declared. \quad \text{(AS 8.2.6)}

- If $V^*$ exceeds its maximum permitted value $\phi V_{u,\max}$, the concrete section size should be increased (AS 8.2.6).
Note that if torsion design is considered and torsion reinforcement is required, the calculated shear reinforcement is ignored. Closed stirrups are designed for combined shear and torsion according to AS 8.3.4(b).

The maximum of all of the calculated $A_{sv}/s$ values obtained from each load combination is reported along with the controlling shear force and associated load combination.

The slab shear reinforcement requirements considered by the program are based purely on shear strength considerations. Any minimum stirrup requirements to satisfy spacing and volumetric considerations must be investigated independently of the program by the user.

5.5.3 Check for Punching Shear

The algorithm for checking punching shear is detailed in the section entitled “Slab Punching Shear Check” in the Chapter 1. Only the code-specific items are described in the following sections.

5.5.3.1 Critical Section for Punching Shear

The punching shear is checked on a critical section at a distance of $d_{col}/2$ from the face of the support (AS 9.2.1.1). For rectangular columns and concentrated loads, the critical area is taken as a rectangular area with the sides parallel to the sides of the columns or the point loads (AS 9.2.1.3). Figure 5-3 shows the auto punching perimeters considered by ETABS for the various column shapes. The column location (i.e., interior, edge, corner) and the punching perimeter may be overwritten using the Punching Check Overwrites.
5.5.3.2 Determine Concrete Capacity

The shear capacity, $f_{cv}$, is calculated based on the minimum of the two expressions from AS 9.2.3, as shown, with the $d_{om}$ and $u$ terms removed to convert force to stress.

\[
f_{cv} = \min \left\{ 0.17 \left( 1 + \frac{2}{\beta_h} \right) \sqrt{f_c}, \quad 0.34 \sqrt{f_c} \right\} \quad \text{(AS 9.2.3(a))}
\]

where, $\beta_h$ is the ratio of the longest dimension to the shortest dimension of the critical section.

5.5.3.3 Determine Maximum Shear Stress

The maximum design shear stress is computed along the major and minor axis of column separately using the following equation:
**5.5.3.4 Determine Capacity Ratio**

The ratio of the maximum shear stress and the concrete punching shear stress capacity is reported as the punching shear capacity ratio by ETABS. If this ratio exceeds 1.0, punching shear reinforcement is designed as described in the following section.

**5.5.4 Design Punching Shear Reinforcement**

The design guidelines for shear links or shear studs are not available in AS 3600-2009. ETABS uses the NZS 3101-06 guidelines to design shear studs or shear links.

The use of shear studs as shear reinforcement in slabs is permitted, provided that the effective depth of the slab is greater than or equal to 150 mm, and not less than 16 times the shear reinforcement bar diameter (NZS 12.7.4.1). If the slab thickness does not meet these requirements, the punching shear reinforcement is not designed and the slab thickness should be increased by the user.

The algorithm for designing the required punching shear reinforcement is used when the punching shear capacity ratio exceeds unity. The *Critical Section for Punching Shear* and *Transfer of Unbalanced Moment* as described in the earlier sections remain unchanged. The design of punching shear reinforcement is carried out as described in the subsections that follow.

**5.5.4.1 Determine Concrete Shear Capacity**

The concrete punching shear stress capacity of a section with punching shear reinforcement is as previously determined for the punching check.

**5.5.4.2 Determine Required Shear Reinforcement**

The shear force is limited to a maximum of:

\[
V_{\text{max}} = 3 \frac{V^*}{ud_{om}} \left[ 1.0 + \frac{uM_v}{8V^*ad_{om}} \right]
\]  

(AS 9.2.4(a))

\[
V_{\text{max}} = 3 \  V_{u,\text{min}} = 3^*V_u
\]

(AS 9.2.4(a), (d))
where $V_u$ is computed from AS 9.2.3 or 9.2.4. Given $V^*$, $V_u$, and $V_{u,\text{max}}$, the required shear reinforcement is calculated as follows, where, $\phi$ is the strength reduction factor.

$$A_{sv} = \frac{(V^* - \phi V_u)}{f_{sv} d_{om}},$$

(AS 8.2.10)

Minimum punching shear reinforcement should be provided such that:

$$V_s \geq \frac{1}{16} \sqrt{f'_{ctd} u d_{om}}$$

(NZS 12.7.4.3)

- If $V^* > \phi V_{\text{max}}$, a failure condition is declared. (NZS 12.7.3.4)
- If $V^*$ exceeds the maximum permitted value of $\phi V_{\text{max}}$, the concrete section should be increased in size.

5.5.4.3 Determine Reinforcement Arrangement

Punching shear reinforcement in the vicinity of rectangular columns should be arranged on peripheral lines, i.e., lines running parallel to and at constant distances from the sides of the column. Figure 5-4 shows a typical arrangement of shear reinforcement in the vicinity of a rectangular interior, edge, and corner column.

The distance between the column face and the first line of shear reinforcement shall not exceed $d/2$. The spacing between adjacent shear reinforcement in the first line (perimeter) of shear reinforcement shall not exceed $2d$ measured in a direction parallel to the column face (NZS 12.7.4.4).

Punching shear reinforcement is most effective near column corners where there are concentrations of shear stress. Therefore, the minimum number of lines of shear reinforcement is 4, 6, and 8, for corner, edge, and interior columns respectively.
5.5.4.4 Determine Reinforcement Diameter, Height, and Spacing

The punching shear reinforcement is most effective when the anchorage is close to the top and bottom surfaces of the slab. The cover of anchors should not be less than the minimum cover specified in NZS 3.11 plus one-half of the diameter of the flexural reinforcement.

When specifying shear studs, the distance, $s_o$, between the column face and the first peripheral line of shear studs should not be smaller than $0.5d$. The spacing between adjacent shear studs, $g$, at the first peripheral line of studs shall not exceed $2d$ and in the case of studs in a radial pattern, the angle between adjacent stud rails shall not exceed 60 degrees. The limits of $s_o$ and the spacing, $s$, between the peripheral lines are specified as:

$$s_o \leq 0.5d$$  \hspace{1cm} (NZS 12.7.4.4)

$$s \leq 0.5d$$  \hspace{1cm} (NZS 12.7.4.4)

$$g \leq 2d$$  \hspace{1cm} (NZS 12.7.4.4)
Chapter 6
Design for AS 3600-01

This chapter describes in detail the various aspects of the concrete design procedure that is used by ETABS when the Australian code AS 3600-2001 [AS 2001] is selected. Various notations used in this chapter are listed in Table 6-1. For referencing to the pertinent sections of the AS code in this chapter, a prefix “AS” followed by the section number is used.

The design is based on user-specified load combinations. The program provides a set of default load combinations that should satisfy the requirements for the design of most building type structures.

English as well as SI and MKS metric units can be used for input. The code is based on Newton-millimeter-second units. For simplicity, all equations and descriptions presented in this chapter correspond to Newton-millimeter-second units unless otherwise noted.

6.2 Design Load Combinations

The design load combinations are the various combinations of the load cases for which the structure needs to be designed. For AS 3600-01, if a structure is subjected to dead (D), live (L), pattern live (PL), snow (S), wind (W), and earthquake (E) loads, and considering that wind and earthquake forces are reversible, the following load combinations may need to be defined (AS 3.3.1):

1.35D  
1.2D + 1.5L  
1.2D + 1.5(0.75 PL)  
1.2D + 0.4L + 1.0S  
0.9D ± 1.0W  
1.2D ± 1.0W  
1.2D + 0.4L ± 1.0W  
1.0D ± 1.0E  
1.0D + 0.4L ± 1.0E

Note that the 0.4 factor on the live load in three of the combinations is not valid for live load representing storage areas. These are also the default design load combinations in ETABS whenever the AS 3600-2001 code is used. If roof live load is treated separately or other types of loads are present, other appropriate load combinations should be used.
6.3 Limits on Material Strength

The upper and lower limits of $f'_c$ are 65 MPa and 20 MPa, respectively, for all framing types (AS 6.1.1.1(b)).

$$f'_c \leq 65 \text{ MPa} \quad (\text{AS 6.1.1.1})$$

$$f'_c \geq 20 \text{ MPa} \quad (\text{AS 6.1.1.1})$$

The upper limit of $f_{sy}$ is 500 MPa for all frames (AS 6.2.1, Table 6.2.1).

The code allows use of $f'_c$ and $f_{sy}$ beyond the given limits, provided special care is taken regarding the detailing and ductility (AS 6.1.1, 6.2.1, 19.2.1.1).

ETABS enforces the upper material strength limits for flexure and shear design of slabs. The input material strengths are taken as the upper limits if they are defined in the material properties as being greater than the limits. The user is responsible for ensuring that the minimum strength is satisfied.

6.4 Strength Reduction Factors

The strength reduction factor, $\phi$, is defined as given in AS 2.3(c), Table 2.3:

$$\phi = 0.80 \text{ for flexure (tension controlled)} \quad (\text{AS 2.3(c)})$$

$$\phi = 0.70 \text{ for shear and torsion} \quad (\text{AS 2.3(c)})$$

These values can be overwritten; however, caution is advised.

6.5 Slab Design

ETABS slab design procedure involves defining sets of strips in two mutually perpendicular directions. The locations of the strips are usually governed by the locations of the slab supports. The axial force, moments and shears for a particular strip are recovered from the analysis (on the basis of the Wood-Armer technique), and a flexural design is carried out based on the ultimate strength design method.
The slab design procedure involves the following steps:

- Design flexural reinforcement
- Design shear reinforcement
- Punching check

6.5.1 Design Flexural Reinforcement

For slabs, ETABS uses either design strips or the finite element based design to calculate the slab flexural reinforcement in accordance with the selected design code. For simplicity, only strip-by-strip design is documented in the proceeding sections.

The design of the slab reinforcement for a particular strip is carried out at specific locations along the length of the strip. These locations correspond to the element boundaries. Controlling reinforcement is computed on either side of those element boundaries. The slab flexural design procedure for each load combination involves the following:

- Determine factored axial loads and moments for each slab strip.
- Design flexural reinforcement for the strip.
- These two steps, described in the text that follows, are repeated for every load combination. The maximum reinforcement calculated for the top and bottom of the slab within each design strip, along with the corresponding controlling load combination, is obtained and reported.

6.5.1.1 Determine Factored Moments

In the design of flexural reinforcement of concrete slab, the factored moments for each load combination at a particular design strip are obtained by factoring the corresponding moments for different load cases, with the corresponding load factors.

The slab is then designed for the maximum positive and maximum negative factored moments obtained from all of the load combinations. Calculation of bottom reinforcement is based on positive design strip moments. In such cases, the slab
may be designed as a rectangular or flanged slab section. Calculation of top reinforcement is based on negative design strip moments. In such cases, the slab may be designed as a rectangular or inverted flanged slab section.

### 6.5.1.2 Determine Required Flexural Reinforcement

In the flexural reinforcement design process, the program calculates both the tension and compression reinforcement. Compression reinforcement is added when the applied design moment exceeds the maximum moment capacity of a singly reinforced section. The user has the option of avoiding compression reinforcement by increasing the effective depth, the width, or the strength of the concrete. Note that the flexural reinforcement strength, $f_y$, is limited to 500MPa (AS 6.2.1), even if the material property is defined using a higher value.

The design procedure is based on the simplified rectangular stress block, as shown in Figure 6-1 (AS 8.1.2.2).

The following assumptions are used for the stress block used to compute the flexural bending capacity of rectangular sections (AS 8.1.2.2).

- The maximum strain in the extreme compression fiber is taken as 0.003.
- A uniform compressive stress of $0.85f'_c$ acts on an area bounded by:
  - The edges of the cross-sections.
  - A line parallel to the neutral axis at the strength limit under the loading concerned, and located at a distance $\gamma k_u d$ from the extreme compression fiber.

The maximum allowable depth of the rectangular compression block, $a_{max}$, is given by

$$a_{max} = \gamma k_u d \quad \text{where,}$$

$$\gamma = \left[0.85 - 0.007(f'_c - 28)\right]$$

$$0.65 \leq \gamma \leq 0.85$$

$$k_u = 0.4$$

(AS 8.1.2.2)
The design procedure used by ETABS for both rectangular and flanged sections (L- and T-shaped sections) is summarized in the following subsections. It is assumed that the design ultimate axial force does not exceed \( (A_v f_y > 0.15 N^0) \) (AS 10.7.1a); hence, all slabs are designed for major direction flexure, shear, and torsion only.

### 6.5.1.3 Design of uniform thickness slab

In designing for a factored negative or positive moment, \( M' \) (i.e., designing top or bottom reinforcement), the depth of the compression block is given by \( a \) (see Figure 6-1), where,

\[
a = d - \sqrt{d^2 - \frac{2|M'|}{0.85 f'_c \phi b}}
\]  

\[\text{(AS 8.1.2.2)}\]

where, the value of \( \phi \) is taken as that for a tension controlled section \( (k_u \leq 0.4) \), which by default is 0.80 (AS 2.3) in the preceding and following equations.

![Figure 6-1 Uniform Thickness Slab Design](image-url)
If \( a \leq a_{\text{max}} \), the area of tension reinforcement is then given by:

\[
A_{\text{tr}} = \frac{M_{\ast}}{\phi f_{y} \left( d - \frac{a}{2} \right)}
\]

This reinforcement is to be placed at the bottom if \( M_{\ast} \) is positive, or at the top if \( M_{\ast} \) is negative.

If \( a > a_{\text{max}} \), i.e., \( k_{u} > 0.4 \), compression reinforcement is required (AS 8.1.3) and is calculated as follows:

The compressive force developed in the concrete alone is given by:

\[
C = 0.85 f'_{c} ba_{\text{max}} \tag{AS 8.1.2.2}
\]

and the moment resisted by concrete compression and tension reinforcement is:

\[
M_{uc} = C \left( d - \frac{a_{\text{max}}}{2} \right) \phi
\]

Therefore, the moment required to be resisted by compression reinforcement and tension reinforcement is:

\[
M_{ur} = M_{\ast} - M_{uc}
\]

The required compression reinforcement is given by:

\[
A_{sc} = \frac{M_{ur}}{(f'_{s} - 0.85 f'_{c}) (d - d') \phi}, \text{ where}
\]

\[
f'_{s} = 0.003 E_{s} \left[ \frac{c - d'}{c} \right] \leq f_{sy} \tag{AS 8.1.2.1, 6.2.2}
\]

The required tension reinforcement for balancing the compression in the concrete is:
and the tension reinforcement for balancing the compression reinforcement is given by:

\[ A_{s2} = \frac{M_{us}}{f_y (d - d') \phi} \]

Therefore, the total tension reinforcement is \( A_{sT} = A_{s1} + A_{s2} \), and the total compression reinforcement is \( A_{sc} \). \( A_{sT} \) is to be placed at the bottom and \( A_{sc} \) is to be placed at the top if \( M^* \) is positive, and vice versa if \( M^* \) is negative.

6.5.1.4 Design of nonuniform thickness slab

In designing a flanged shaped section, a simplified stress block, as shown in Figure 6-2, is assumed if the flange is under compression, i.e., if the moment is positive. If the moment is negative, the flange comes under tension, and the flange is ignored. In that case, a simplified stress block similar to that shown in Figure 6-1 is assumed on the compression side (AS 8.1.3).

![Figure 6-2 T- Nonuniform Thickness Slab Design](image)
6.5.1.4.1.1 Flanged Slab Section Under Negative Moment

In designing for a factored negative moment, $M^*$ (i.e., designing top reinforcement), the calculation of the reinforcement is exactly the same as above, i.e., no flanged data is used.

6.5.1.4.1.2 Flanged Slab Section Under Positive Moment

If $M^* > 0$, the depth of the compression block is given by:

$$a = d - \sqrt{d^2 - \frac{2M^*}{0.85f'_c \phi b_f}}$$

where, the value of $\phi$ is taken as that for $k_u \leq 0.4$, which is 0.80 by default (AS 2.3) in the preceding and the following equations.

The maximum allowable depth of the rectangular compression block, $a_{\text{max}}$, is given by:

$$a_{\text{max}} = \gamma k_u d \text{ where, } k_u = 0.4 \quad \text{(AS 8.1.3)}$$

- If $a \leq D_s$, the subsequent calculations for $A_{st}$ are exactly the same as previously defined for the uniform thickness slab design. However, in that case, the width of the slab is taken as $b_f$. Compression reinforcement is required when $a > a_{\text{max}}$.

- If $a > D_s$, the calculation for $A_{st}$ has two parts. The first part is for balancing the compressive force from the flange, $C_f$, and the second part is for balancing the compressive force from the web, $C_w$, as shown in Figure 6-2. $C_f$ is given by:

$$C_f = 0.85f'_c \left(b_{sf} - b_w\right) \times \min(D_s, a_{\text{max}}) \quad \text{(AS 8.1.2.2)}$$

Therefore, $A_{st} = \frac{C_f}{f_{sy}}$ and the portion of $M^*$ that is resisted by the flange is given by:

$$M_{uf} = \phi C_f \left(d - \frac{\min(D_s, a_{\text{max}})}{2}\right)$$

Therefore, the balance of the moment, $M^*$ to be carried by the web is:
ETABS Reinforced Concrete Design

\[ M_{uw} = M' - M_{uf} \]

The web is a rectangular section of dimensions \( b_w \) and \( d \), for which the design depth of the compression block is recalculated as:

\[ a_1 = d - \sqrt{d^2 - \frac{2M_{uw}}{0.85 f'_c \phi b_w}} \]

- If \( a_1 \leq a_{\text{max}} \), the area of tension reinforcement is then given by:

\[
A_{s2} = \frac{M_{uw}}{\phi f_{sy} \left( d - \frac{a_1}{2} \right)}, \text{ and} \quad A_{st} = A_{s1} + A_{s2}
\]

This reinforcement is to be placed at the bottom of the flanged slab.

- If \( a_1 > a_{\text{max}} \), compression reinforcement is required and is calculated as follows:

The compression force in the web concrete alone is given by:

\[ C_w = 0.85 f'_c b_w a_{\text{max}} \quad \text{(AS 8.1.2.2)} \]

Therefore the moment resisted by the concrete web and tension reinforcement is:

\[ M_{wc} = C_w \left( d - \frac{a_{\text{max}}}{2} \right) \phi \]

and the moment resisted by compression and tension reinforcement is:

\[ M_{ws} = M_{uw} - M_{wc} \]

Therefore, the compression reinforcement is computed as:

\[ A_{wc} = \frac{M_{ws}}{(f'_s - 0.85 f'_c)(d - d') \phi}, \text{ where} \]

6 - 12  Slab Design
6.5.1.5 Minimum and Maximum Reinforcement

The minimum flexural tensile reinforcement required for each direction of a slab is given by the following limits (AS 9.1.1):

\[
A_s \geq 0.0025 \, bh \quad \text{for flat slabs} \quad \text{(AS 9.1.1(a))}
\]

\[
A_s \geq 0.0020 \, bh \quad \text{for slabs supported by beams/walls and slab footings} \quad \text{(AS 9.1.1(b))}
\]

In addition, an upper limit on both the tension reinforcement and compression reinforcement has been imposed to be 0.04 times the gross cross-sectional area.

6.5.2 Design Slab Shear Reinforcement

The shear reinforcement is designed for each load combination at each station along the design strip. In designing the shear reinforcement for a particular strip, for a particular load combination, at a particular station due to the slab major shear, the following steps are involved:
ETABS Reinforced Concrete Design

- Determine the factored shear force, \( V' \).
- Determine the shear force, \( V_{uc} \), that can be resisted by the concrete.
- Determine the shear reinforcement required to carry the balance.

The following three sections describe in detail the algorithms associated with these steps.

### 6.5.2.1 Determine Shear Force

In the design of the slab shear reinforcement, the shear forces for each load combination at a particular design strip station are obtained by factoring the corresponding shear forces for different load cases, with the corresponding load combination factors.

### 6.5.2.2 Determine Concrete Shear Capacity

The shear force carried by the concrete, \( V_{uc} \), is calculated as:

\[
V_{uc} = \beta_1 \beta_2 \beta_3 b_w d_o \left[ \frac{A_g f'_c}{b_w d_o} \right]^{1/3}
\]  

(AS 8.2.7.1)

where,

\[
\beta_1 = 1.1 \left( 1.6 - \frac{d_o}{1000} \right) \geq 1.1
\]  

(AS 8.2.7.1)

\[
\beta_2 = 1, \text{ or }
\]

\[
\beta_3 = \begin{cases} 1 & \text{for members subject to significant axial tension, or} \\ 1 + \left( \frac{N^*}{14 A_g} \right) & \text{for members subject to significant axial compression.} \\ 1 & \end{cases}
\]
6.5.2.3 Determine Required Shear Reinforcement

The shear force is limited to:

\[ V_{u, \text{min}} = V_{uc} + 0.6b_v d_o \]  \hspace{1cm} (AS 8.2.9)

\[ V_{u, \text{max}} = 0.2 f'_{c} b d_o \]  \hspace{1cm} (AS 8.2.6)

Given \( V^*, V_{uc}, \) and \( V_{u, \text{max}}, \) the required shear reinforcement is calculated as follows, where, \( \phi, \) the strength reduction factor, is 0.6 by default (AS 2.3).

- If \( V^* \leq \phi V_{uc} / 2, \)
  \[ \frac{A_{sv}}{s} = 0, \]  \hspace{1cm} if \( D \leq 750 \text{ mm}; \) otherwise \( A_{sv, \text{min}} \) shall be provided. \hspace{1cm} (AS 8.2.5).

- If \( (\phi V_{uc} / 2) < V^* \leq \phi V_{u, \text{min}}, \)
  \[ \frac{A_{sv}}{s} = 0, \]  \hspace{1cm} if \( D < b_w / 2 \) or 250 mm, whichever is greater (AS 8.2.5(c)(i)); otherwise \( A_{sv, \text{min}} \) shall be provided.

- If \( \phi V_{u, \text{min}} < V^* \leq \phi V_{u, \text{max}}, \)
  \[ \frac{A_{sv}}{s} = \left( \frac{V^* - \phi V_{uc}}{\phi f_{sy, f} d_o \cot \theta_v} \right), \] \hspace{1cm} (AS 8.2.10)

and greater than \( A_{sv, \text{min}}, \) defined as:

\[ \frac{A_{sv, \text{min}}}{s} = \left( 0.35 \frac{b_w}{f_{sy, f}} \right) \] \hspace{1cm} (AS 8.2.8)

\( \theta_v = \) the angle between the axis of the concrete compression strut and the longitudinal axis of the member, which varies linearly from 30 degrees when \( V^* = \phi V_{u, \text{min}} \) to 45 degrees when \( V^* = \phi V_{u, \text{max}}. \)

- If \( V^* > \phi V_{\text{max}}, \) a failure condition is declared. \hspace{1cm} (AS 8.2.6)
- If $V^c$ exceeds its maximum permitted value $\phi V_{\text{max}}$, the concrete section size should be increased (AS 8.2.6).

Note that if torsion design is considered and torsion reinforcement is required, the calculated shear reinforcement is ignored. Closed stirrups are designed for combined shear and torsion according to AS 8.3.4(b).

The maximum of all of the calculated $A_{sv}/s$ values obtained from each load combination is reported along with the controlling shear force and associated load combination.

The slab shear reinforcement requirements considered by the program are based purely on shear strength considerations. Any minimum stirrup requirements to satisfy spacing and volumetric considerations must be investigated independently of the program by the user.

### 6.5.3 Check for Punching Shear

The algorithm for checking punching shear is detailed in the section entitled “Slab Punching Shear Check” in the Chapter 1. Only the code-specific items are described in the following sections.

#### 6.5.3.1 Critical Section for Punching Shear

The punching shear is checked on a critical section at a distance of $d_{\text{om}}/2$ from the face of the support (AS 9.2.1.1). For rectangular columns and concentrated loads, the critical area is taken as a rectangular area with the sides parallel to the sides of the columns or the point loads (AS 9.2.1.3). Figure 6-3 shows the auto punching perimeters considered by ETABS for the various column shapes. The column location (i.e., interior, edge, corner) and the punching perimeter may be overwritten using the Punching Check Overwrites.
6.5.3.2 Determine Concrete Capacity

The shear capacity, $f_{sv}$, is calculated based on the minimum of the two expressions from AS 3600-01 equation 11-35, as shown, with the $d_{om}$ and $u$ terms removed to convert force to stress.

$$f_{sv} = \min\left\{ 0.17\left(1 + \frac{2}{\beta_h}\right)\sqrt{f'_c}, 0.34\sqrt{f'_c} \right\} \quad \text{(AS 9.2.3(a))}$$

where, $\beta_h$ is the ratio of the longest dimension to the shortest dimension of the critical section.

6.5.3.3 Determine Maximum Shear Stress

The maximum design shear stress is computed along the major and minor axis of column separately using the following equation:
ETABS Reinforced Concrete Design

\[
v_{\text{max}} = \frac{V^*}{ud_{\text{om}}} \left[ 1.0 + \frac{uM_v}{8V^*ad_{\text{om}}} \right]
\]

(AS 9.2.4(a))

6.5.3.4 Determine Capacity Ratio

The ratio of the maximum shear stress and the concrete punching shear stress capacity is reported as the punching shear capacity ratio by ETABS. If this ratio exceeds 1.0, punching shear reinforcement is designed as described in the following section.

6.5.4 Design Punching Shear Reinforcement

The design guidelines for shear links or shear studs are not available in AS 3600-2001. ETABS uses the NZS 3101-06 guidelines to design shear studs or shear links.

The use of shear studs as shear reinforcement in slabs is permitted, provided that the effective depth of the slab is greater than or equal to 150 mm, and not less than 16 times the shear reinforcement bar diameter (NZS 12.7.4.1). If the slab thickness does not meet these requirements, the punching shear reinforcement is not designed and the slab thickness should be increased by the user.

The algorithm for designing the required punching shear reinforcement is used when the punching shear capacity ratio exceeds unity. The Critical Section for Punching Shear and Transfer of Unbalanced Moment as described in the earlier sections remain unchanged. The design of punching shear reinforcement is carried out as described in the subsections that follow.

6.5.4.1 Determine Concrete Shear Capacity

The concrete punching shear stress capacity of a section with punching shear reinforcement is as previously determined for the punching check.

6.5.4.2 Determine Required Shear Reinforcement

The shear force is limited to a maximum of:

\[
V_{\text{max}} = 3 \ V_{u,\text{min}} = 3*V_u
\]

(AS 92.2.4(a), (d))
where $V_u$ is computed from AS 9.2.3 or 9.2.4. Given $V^*$, $V_u$, and $V_{u,max}$, the required shear reinforcement is calculated as follows, where, $\phi$ is the strength reduction factor.

$$\frac{A_{sv}}{s} = \frac{(V^* - \phi V_u)}{f_{sy} a_{em}}$$  

(AS 8.2.10)

Minimum punching shear reinforcement should be provided such that:

$$V_s \geq \frac{1}{16} \sqrt{f'_{cd} u d_{em}}$$  

(NZS 12.7.4.3)

- If $V^* > \phi V_{max}$, a failure condition is declared.  

(NZS 12.7.3.4)

- If $V^*$ exceeds the maximum permitted value of $\phi V_{max}$, the concrete section should be increased in size.

### 6.5.4.3 Determine Reinforcement Arrangement

Punching shear reinforcement in the vicinity of rectangular columns should be arranged on peripheral lines, i.e., lines running parallel to and at constant distances from the sides of the column. Figure 6-4 shows a typical arrangement of shear reinforcement in the vicinity of a rectangular interior, edge, and corner column.

The distance between the column face and the first line of shear reinforcement shall not exceed $d/2$. The spacing between adjacent shear reinforcement in the first line (perimeter) of shear reinforcement shall not exceed $2d$ measured in a direction parallel to the column face (NZS 12.7.4.4).

Punching shear reinforcement is most effective near column corners where there are concentrations of shear stress. Therefore, the minimum number of lines of shear reinforcement is 4, 6, and 8, for corner, edge, and interior columns respectively.
6.5.4.4 **Determine Reinforcement Diameter, Height, and Spacing**

The punching shear reinforcement is most effective when the anchorage is close to the top and bottom surfaces of the slab. The cover of anchors should not be less than the minimum cover specified in NZS 3.11 plus half of the diameter of the flexural reinforcement.

When specifying shear studs, the distance, $s_o$, between the column face and the first peripheral line of shear studs should not be smaller than $0.5d$. The spacing between adjacent shear studs, $g$, at the first peripheral line of studs shall not exceed $2d$ and in the case of studs in a radial pattern, the angle between adjacent stud rails shall not exceed 60 degrees. The limits of $s_o$ and the spacing, $s$, between the peripheral lines are specified as:

\[
s_o \leq 0.5d \quad \text{(NZS 12.7.4.4)}
\]
\[
s \leq 0.5d \quad \text{(NZS 12.7.4.4)}
\]
\[
g \leq 2d \quad \text{(NZS 12.7.4.4)}
\]
This chapter describes in detail the various aspects of the concrete design procedure that is used by ETABS when the British code BS 8110-1997 [BSI 1997] is selected. For lightweight concrete and torsion, reference is made to BS 8110-2:1985 [BSI 1985]. Various notations used in this chapter are listed in Table 7-1. For referencing to the pertinent sections of the British code BS 8110-1997 in this chapter, a prefix “BS” followed by the section number is used.

The design is based on user-specified loading combinations. The program provides a set of default load combinations that should satisfy the requirements for the design of most building type structures.

English as well as SI and MKS metric units can be used for input. The code is based on Newton-millimeter-second units. For simplicity, all equations and descriptions presented in this chapter correspond to Newton-millimeter-second units unless otherwise noted.

### 7.2 Design Load Combinations

The design load combinations are the various combinations of the load cases for which the structure needs to be designed. The design load combinations are obtained by multiplying the characteristic loads by appropriate partial factors of safety, $\gamma_f$ (BS 2.4.1.3). For BS 8110-1997, if a structure is subjected to dead (D), live (L), pattern live (PL), snow (S), and wind (W) loads, and considering that wind forces are reversible, the following load combinations may need to be considered (BS 2.4.3):

1. $1.4D$
2. $1.4D + 1.6L$
3. $1.4D + 1.6(0.75PL)$
4. $1.0D \pm 1.4W$
5. $1.4D \pm 1.4W$
6. $1.2D + 1.2L \pm 1.2W$

(BS 2.4.3)
Chapter 7 - Design for BS 8110-97

1.4D + 1.6L + 1.6S
1.2D + 1.2S ± 1.2W
1.2D + 1.2L + 1.2S ± 1.2W

(BS 2.4.3)

These are also the default design load combinations in ETABS whenever the BS 8110-1997 code is used. If roof live load is treated separately or other types of loads are present, other appropriate load combinations should be used. Note that the automatic combination, including pattern live load, is assumed and should be reviewed before using for design.

7.3 Limits on Material Strength

The concrete compressive strength, $f_{cu}$, should not be less than 25 MPa (BS 3.1.7.2). ETABS does not enforce this limit for flexure and shear design of slabs. The input material strengths are used for design even if they are outside of the limits. It is the user's responsibility to use the proper strength values while defining the materials.

7.4 Partial Safety Factors

The design strengths for concrete and reinforcement are obtained by dividing the characteristic strength of the material by a partial safety factor, $\gamma_m$. The values of $\gamma_m$ used in the program are listed in the following table, as taken from BS Table 2.2 (BS 2.4.4.1):

<table>
<thead>
<tr>
<th></th>
<th>$\gamma_m$</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reinforcement</td>
<td>1.15</td>
</tr>
<tr>
<td>Concrete in flexure and axial load</td>
<td>1.50</td>
</tr>
<tr>
<td>Concrete shear strength without shear reinforcement</td>
<td>1.25</td>
</tr>
</tbody>
</table>

These factors are already incorporated into the design equations and tables in the code. Note that for reinforcement, the default factor of 1.15 is for Grade 500 reinforcement. If other grades are used, this value should be overwritten as necessary. Changes to the partial safety factors are carried through the design equations where necessary, typically affecting the material strength portions of the equations.
7.5 Slab Design

ETABS slab design procedure involves defining sets of strips in two mutually perpendicular directions. The locations of the strips are usually governed by the locations of the slab supports. The axial force, moments and shears for a particular strip are recovered from the analysis (on the basis of the Wood-Armer technique), and a flexural design is carried out based on the ultimate strength design method.

The slab design procedure involves the following steps:

- Design flexural reinforcement
- Design shear reinforcement
- Punching check

7.5.1 Design Flexural Reinforcement

For slabs, ETABS uses either design strips or the finite element based design to calculate the slab flexural reinforcement in accordance with the selected design code. For simplicity, only strip-by-strip design is document in the proceeding sections.

The design of the slab reinforcement for a particular strip is carried out at specific locations along the length of the strip. These locations correspond to the element boundaries. Controlling reinforcement is computed on either side of those element boundaries. The slab flexural design procedure for each load combination involves the following:

- Determine factored axial loads and moments for each slab strip.
- Design flexural reinforcement for the strip.
- These two steps, described in the text that follows, are repeated for every load combination. The maximum reinforcement calculated for the top and bottom of the slab within each design strip, along with the corresponding controlling load combination, is obtained and reported.
7.5.1.1 Determine Factored Moments

In the design of flexural reinforcement of concrete slab, the factored moments for each load combination at a particular design strip are obtained by factoring the corresponding moments for different load cases, with the corresponding load factors.

The slab is then designed for the maximum positive and maximum negative factored moments obtained from all of the load combinations. Calculation of bottom reinforcement is based on positive design strip moments. In such cases, the slab may be designed as a rectangular or flanged slab section. Calculation of top reinforcement is based on negative design strip moments. In such cases, the slab may be designed as a rectangular or inverted flanged slab section.

7.5.1.2 Determine Required Flexural Reinforcement

In the flexural reinforcement design process, the program calculates both the tension and compression reinforcement. Compression reinforcement is added when the applied design moment exceeds the maximum moment capacity of a singly reinforced section. The user has the option of avoiding the compression reinforcement by increasing the effective depth, the width, or the strength of the concrete.

The design procedure is based on the simplified rectangular stress block shown in Figure 7-1 (BS 3.4.4.4). Furthermore, it is assumed that moment redistribution in the member does not exceed 10% (i.e., $\beta_b \geq 0.9$; BS 3.4.4.4). The code also places a limitation on the neutral axis depth, $x/d \leq 0.5$, to safeguard against non-ductile failures (BS 3.4.4.4). In addition, the area of compression reinforcement is calculated assuming that the neutral axis depth remains at the maximum permitted value.

The design procedure used by ETABS, for both rectangular and flanged sections (L- and T-shaped section) is summarized in the subsections that follow. It is assumed that the design ultimate axial force does not exceed $(0.1f_{cu} A_g)$ (BS 3.4.4.1); hence, all slabs are designed for major direction flexure, shear, and torsion only.
Design of uniform thickness slab

For uniform thickness slab, the limiting moment capacity as a singly reinforced slab, \( M_{\text{single}} \), is first calculated for a section. The reinforcement is determined based on \( M \) being greater than, less than, or equal to \( M_{\text{single}} \). See Figure 7-1.

- Calculate the ultimate limiting moment of resistance of the section as singly reinforced.

\[
M_{\text{single}} = K' f_{cu} bd^2
\]

where \( K' = 0.156 \) (BS 3.4.4.4)

- If \( M \leq M_{\text{single}} \), the area of tension reinforcement, \( A_s \), is given by:

\[
A_s = \frac{M}{0.87 f_y d} \text{, where}
\]

(Figure 7-1 Uniform Thickness Slab Design)
This reinforcement is to be placed at the bottom if $M$ is positive, or at the top if $M$ is negative.

- If $M > M_{\text{single}}$, compression reinforcement is required and calculated as follows:

$$A'_{s} = \frac{M - M_{\text{single}}}{f'_{s} - 0.67f_{\text{cu}} \gamma_{c}}(d - d')$$

where $d'$ is the depth of the compression reinforcement from the concrete compression face, and

$$f'_{s} = 0.87f_{y} \quad \text{if} \quad \frac{d'}{d} \leq \frac{1}{2} \left[ 1 - \frac{f_{y}}{800} \right]$$

$$f'_{s} = E_{c} \varepsilon_{c} \left[ 1 - \frac{2d'}{d} \right] \quad \text{if} \quad \frac{d'}{d} > \frac{1}{2} \left[ 1 - \frac{f_{y}}{800} \right]$$

The tension reinforcement required for balancing the compression in the concrete and the compression reinforcement is calculated as:

$$A_{s} = \frac{M_{\text{single}}}{0.87f_{y}z} + \frac{M - M_{\text{single}}}{0.87f_{y}(d - d')}, \quad \text{where}$$

$$z = d \left( 0.5 + \sqrt{0.25 - \frac{K'}{0.9}} \right) = 0.777d$$
Design of nonuniform thickness slab

7.5.1.2.2.1 Flanged Slab Section Under Negative Moment

In designing for a factored negative moment, \( M \) (i.e., designing top reinforcement), the calculation of the reinforcement area is exactly the same as described previously, i.e., no flanged data is used.

7.5.1.2.2.2 Flanged Slab Section Under Positive Moment

With the flange in compression, the program analyzes the section by considering alternative locations of the neutral axis. Initially the neutral axis is assumed to be located in the flange. Based on this assumption, the program calculates the exact depth of the neutral axis. If the stress block does not extend beyond the flange thickness, the section is designed as a uniform thickness slab of width \( b_f \). If the stress block extends beyond the flange depth, the contribution of the web to the flexural strength of the slab is taken into account. See Figure 7-2.

Assuming the neutral axis to lie in the flange, the normalized moment is given by:

\[
\varepsilon = 0.0035
\]
\[ K = \frac{M}{f_{cu} b_f d^2} \]  
(BS 3.4.4.4)

Then the moment arm is computed as:

\[ z = d \left\{ 0.5 + \sqrt{0.25 - \frac{K}{0.9}} \right\} \leq 0.95d \]  
(BS 3.4.4.4)

the depth of the neutral axis is computed as:

\[ x = \frac{1}{0.45} (d - z) \]  
(BS 3.4.4.4)

and the depth of the compression block is given by:

\[ a = 0.9x \]  
(BS 3.4.4.4)

- If \( a \leq h_f \), the subsequent calculations for \( A_s \) are exactly the same as previously defined for the uniform thickness slab design. However, in that case, the width of the slab is taken as \( b_f \). Compression reinforcement is required when \( K > K' \).

- If \( a > h_f \), when \( M \leq \beta f_{cu} b_d^2 \) and \( h_f \leq 0.45d \), then

\[ A_s = \frac{M + 0.1 f_{cu} b_d (0.45d - h_f)}{0.87 f_y (d - 0.5h_f)} \text{, where} \]  
(BS 3.4.4.5)

\[ \beta_f = 0.45 \frac{h_f}{d} \left( 1 - \frac{b_w}{b} \right) \left( 1 - \frac{h_f}{2d} \right) + 0.15 \frac{b_w}{b} \]  
(BS 3.4.4.5)

Otherwise the calculation for \( A_s \) has two parts. The first part is for balancing the compressive force from the flange, \( C_f \), and the second part is for balancing the compressive force from the web, \( C_w \), as shown in Figure 7-2.

In that case, the ultimate resistance moment of the flange is given by:

\[ M_f = 0.45 f_{cu} (b_f - b_w) h_f \left( d - 0.5h_f \right) \]  
(BS 3.4.4.5)

The moment taken by the web is computed as:
and the normalized moment resisted by the web is given by:

\[ K_w = \frac{M_w}{f_{cu} b_w d^2} \]  

(BS 3.4.4.4)

- If \( K_w \leq 0.156 \) (BS 3.4.4.4), the slab is designed as a singly reinforced concrete slab. The reinforcement is calculated as the sum of two parts, one to balance compression in the flange and one to balance compression in the web.

\[
A_y = \frac{M_f}{0.87 f_y (d - 0.5 h_f)} + \frac{M_w}{0.87 f_y z}, \quad \text{where}
\]

\[ z = d \left( 0.5 + \sqrt{0.25 - \frac{K_w}{0.9}} \right) \leq 0.95 d \]

- If \( K_w > K' \) (BS 3.4.4.4), compression reinforcement is required and is calculated as follows:

The ultimate moment of resistance of the web only is given by:

\[ M_{uw} = K' f_{cu} b_w d^2 \]  

(BS 3.4.4.4)

The compression reinforcement is required to resist a moment of magnitude \( M_w - M_{uw} \). The compression reinforcement is computed as:

\[
A_y' = \frac{M_w - M_{uw}}{\left( f_y' - \frac{0.67 f_{cu}}{\gamma_c} \right)(d - d')} \]  

(BS 3.4.4.4)

where, \( d' \) is the depth of the compression reinforcement from the concrete compression face, and

\[ f_y' = 0.87 f_y \text{ if } \frac{d'}{d} \leq \frac{1}{2} \left[ 1 - \frac{f_y}{800} \right] \]  

(BS 3.4.4.1, 2.5.3, Fig 2.2)
\[ f'_s = E_s \varepsilon_s \left[ 1 - \frac{2d'}{d} \right] \text{ if } \frac{d'}{d} > \frac{1}{2} \left[ 1 - \frac{f_s}{800} \right] \]  
(BS 3.4.4.1, 2.5.3, Fig 2.2)

The area of tension reinforcement is obtained from equilibrium as:

\[ A_t = \frac{M_f}{0.87f_s(d - 0.5h_f)} + \frac{M_{uw}}{0.87f_s(0.777d)} + \frac{M_{w - M_{uw}}}{0.87f_s(d - d')} \]

7.5.1.3 Minimum and Maximum Slab Reinforcement

The minimum flexural tension reinforcement required for each direction of a slab is given by the following limits (BS 3.12.5.3, BS Table 3.25) with interpolation for reinforcement of intermediate strength:

\[ A_t \geq \begin{cases} 0.0024bh & \text{if } f_s = 250\text{MPa} \\ 0.0013bh & \text{if } f_s = 500\text{MPa} \end{cases} \]  
(BS 3.12.5.3)

In addition, an upper limit on both the tension reinforcement and compression reinforcement has been imposed to be 0.04 times the gross cross-sectional area (BS 3.12.6.1).

7.5.2 Design Slab Shear Reinforcement

The shear reinforcement is designed for each load combination at each station along the design strip. In designing the shear reinforcement for a particular strip, for a particular load combination, at a particular station due to the slab major shear, the following steps are involved:

- Determine the shear stress, \( \nu \).
- Determine the shear stress, \( \nu_c \), that can be resisted by the concrete.
- Determine the shear reinforcement required to carry the balance.

The following three sections describe in detail the algorithms associated with these steps.
7.5.2.1 Determine Shear Stress

In the design of the slab shear reinforcement, the shear forces for each load combination at a particular strip station are obtained by factoring the corresponding shear forces for different load cases with the corresponding load combination factors. The shear stress is then calculated as:

\[ v = \frac{V}{b_d d} \]  
\[ (BS \ 3.4.5.2) \]

The maximum allowable shear stress, \( v_{\text{max}} \) is defined as:

\[ v_{\text{max}} = \min(0.8 \sqrt{f_{\text{cu}}} , \ 5 \text{ MPa}) \]  
\[ (BS \ 3.4.5.2) \]

For light-weight concrete, \( v_{\text{max}} \) is defined as:

\[ v_{\text{max}} = \min(0.63 \sqrt{f_{\text{cu}}} , \ 4 \text{ MPa}) \]  
\[ (BS \ 8110-2:1985 \ 5.4) \]

7.5.2.2 Determine Concrete Shear Capacity

The shear stress carried by the concrete, \( v_c \), is calculated as:

\[ v'_c = v_c + 0.6 \frac{N V h}{A_c M} \leq v_c \left[ 1 + \frac{N}{A_c v_c} \right] \]  
\[ (BS \ 3.4.5.12) \]

\[ v_c = \frac{0.79k_1 k_2 k_3 \left( \frac{100 A_y}{bd} \right)^{1/3} \left( \frac{400}{d} \right)^{1/4}}{\gamma_m} \]  
\[ (BS \ 3.4.5.4, \ Table \ 3.8) \]

\( k_1 \) is the enhancement factor for support compression, and is conservatively taken as 1  
\[ (BS \ 3.4.5.8) \]

\[ k_2 = \left( \frac{f_{\text{cu}}}{25} \right)^{1/3}, \ 1 \leq k_2 \leq \left( \frac{40}{25} \right)^{1/3} \]  
\[ (BS \ 3.4.5.4, \ Table \ 3.8) \]

\[ \gamma_m = 1.25 \]  
\[ (BS \ 2.4.4.1) \]

However, the following limits also apply:
0.15 ≤ \frac{100 A_s}{bd} ≤ 3 \quad \text{(BS 3.4.5.4, Table 3.8)}

\left( \frac{400}{d} \right)^{0.4} \geq 0.67 \text{ (unreinforced) or } \geq 1 \text{ (reinforced)} \quad \text{(BS 3.4.5.4, Table 3.8)}

f_{cu} \leq 40 \text{ MPa (for calculation purposes only)} \quad \text{(BS 3.4.5.4)}

\frac{Vh}{M} \leq 1 \quad \text{(BS 3.4.5.12)}

A_s \text{ is the area of tension reinforcement.}

### 7.5.2.3 Determine Required Shear Reinforcement

Given \( v, v_c, \text{ and } v_{\text{max}} \), the required shear reinforcement is calculated as follows (BS Table 3.8, BS 3.4.5.3):

- If \( v \leq (v' c + 0.4) \),
  \[
  \frac{A_{sv}}{s_v} = \frac{0.4b_w}{0.87f_{sv}}
  \quad \text{(BS 3.4.5.3, Table 3.7)}
  \]

- If \((v' c + 0.4) < v \leq v_{\text{max}}\),
  \[
  \frac{A_{sv}}{s_v} = \frac{(v - v' c)b_w}{0.87f_{sv}}
  \quad \text{(BS 3.4.5.3, Table 3.7)}
  \]

- If \( v > v_{\text{max}} \), a failure condition is declared. \quad \text{(BS 3.4.5.2)}

In the preceding expressions, a limit is imposed on \( f_{sv} \) as:

\[ f_{sv} \leq 500 \text{ MPa.} \quad \text{(BS 3.4.5.1)} \]

The maximum of all of the calculated \( A_{sv}/s_v \) values, obtained from each load combination, is reported along with the controlling shear force and associated load combination.
The slab shear reinforcement requirements considered by the program are based purely on shear strength considerations. Any minimum stirrup requirements to satisfy spacing and volumetric considerations must be investigated independently of the program by the user.

7.5.3 Check for Punching Shear

The algorithm for checking punching shear is detailed in the section entitled “Slab Punching Shear Check” in the Chapter 1. Only the code-specific items are described in the following sections.

7.5.3.1 Critical Section for Punching Shear

The punching shear is checked at the face of the column (BS 3.7.6.4) and at a critical section at a distance of $1.5d$ from the face of the support (BS 3.7.7.6). For rectangular columns and concentrated loads, the critical area is taken as a rectangular area with the sides parallel to the sides of the columns or the point loads (BS 3.7.7.1). Figure 7-3 shows the auto punching perimeters considered by ETABS for the various column shapes. The column location (i.e., interior, edge, corner) and the punching perimeter may be overwritten using the Punching Check Overwrites.
7.5.3.2 Determine Concrete Capacity

The concrete punching shear factored strength is taken as (BS 3.7.7.4, 3.7.7.6):

\[
\nu_c = \frac{0.79 k_1 k_2}{\gamma_m} \left( \frac{100 A_s}{bd} \right)^{\frac{\gamma}{3}} \left( \frac{400}{d} \right)^{\frac{\gamma}{4}}
\]

(BS 3.4.5.4, Table 3.8)

\(k_1\) is the enhancement factor for support compression, and is conservatively taken as 1 (BS 3.4.5.8)

\[k_2 = \left( \frac{f_{cu}}{25} \right)^{\frac{\gamma}{3}}, \quad 1 \leq k_2 \leq \left( \frac{40}{25} \right)^{\frac{\gamma}{3}}\]

(BS 3.4.5.4, Table 3.8)

\(\gamma_m = 1.25\) (BS 3.4.5.2)

However, the following limitations also apply:
\[
0.15 \leq \frac{100 A_s}{bd} \leq 3 \quad \text{(BS 3.4.5.4, Table 3.8)}
\]

\[
\left( \frac{400}{d} \right)^{\frac{1}{4}} \geq 0.67 \text{ (unreinforced) or } \geq 1 \text{ (reinforced)} \quad \text{(BS 3.4.5.4)}
\]

\[
v \leq \min(0.8 \sqrt{f_{cu}}, \ 5\text{MPa}) \quad \text{(BS 3.7.6.4)}
\]

For light-weight concrete, \(v_{\text{max}}\) is defined as:

\[
v \leq \min(0.63 \sqrt{f_{cu}}, \ 4 \text{ MPa}) \quad \text{(BS 8110-2:1985 5.4)}
\]

\(f_{cu} \leq 40\text{ MPa} \) (for calculation purpose only) \(\text{(BS 3.4.5.4)}\)

\(A_s = \) area of tension reinforcement, which is taken as the average tension reinforcement of design strips in Layer A and layer B where Layer A and Layer design strips are in orthogonal directions. When design strips are not present in both orthogonal directions then tension reinforcement is taken as zero in the current implementation.

### 7.5.3.3 Determine Maximum Shear Stress

Given the punching shear force and the fractions of moments transferred by eccentricity of shear about the bending axis, the nominal design shear stress, \(v_{\text{max}}\), is calculated as:

\[
V_{\text{eff}, x} = V \left( f + \frac{1.5 M_x}{V_{yx}} \right) \quad \text{(BS 3.7.6.2, 3.7.6.3)}
\]

\[
V_{\text{eff}, y} = V \left( f + \frac{1.5 M_y}{V_{yx}} \right) \quad \text{(BS 3.7.6.2, 3.7.6.3)}
\]

\[
v_{\text{max}} = \max \left\{ \frac{V_{\text{eff}, x}}{u d}, \frac{V_{\text{eff}, y}}{u d} \right\} \quad \text{(BS 3.7.7.3)}
\]
where,

\( u \) is the perimeter of the critical section

\( x \) and \( y \) are the lengths of the sides of the critical section parallel to the axis of bending

\( M_x \) and \( M_y \) are the design moments transmitted from the slab to the column at the connection

\( V \) is the total punching shear force

\( f \) is a factor to consider the eccentricity of punching shear force and is taken as:

\[
 f = \begin{cases} 
 1.00 & \text{for interior columns} \\
 1.25 & \text{for edge columns} \\
 1.25 & \text{for corner columns} 
\end{cases} 
\]

(BS 3.7.6.2, 3.7.6.3)

7.5.3.4 Determine Capacity Ratio

The ratio of the maximum shear stress and the concrete punching shear stress capacity is reported as the punching shear capacity ratio by ETABS. If this ratio exceeds 1.0, punching shear reinforcement is designed as described in the following section.

7.5.4 Design Punching Shear Reinforcement

The use of shear studs as shear reinforcement in slabs is permitted, provided that the effective depth of the slab is greater than or equal to 200 mm (BS 3.7.7.5). If the slab thickness does not meet these requirements, the punching shear reinforcement is not designed and the slab thickness should be increased by the user.

The algorithm for designing the required punching shear reinforcement is used when the punching shear capacity ratio exceeds unity. The Critical Section for Punching Shear and Transfer of Unbalanced Moment as described in the earlier sections remain unchanged. The design of punching shear reinforcement is carried out as explained in the subsections that follow.
7.5.4.1 Determine Concrete Shear Capacity

The concrete punching shear stress capacity of a section with punching shear reinforcement is as previously determined for the punching check.

7.5.4.2 Determine Required Shear Reinforcement

The shear stress is limited to a maximum of:

\[ v_{\text{max}} = 2v_c \]  

Given \( v, v_c, \) and \( v_{\text{max}} \), the required shear reinforcement is calculated as follows (BS 3.7.7.5).

- If \( v \leq 1.6v_c \),
  \[ \frac{A_v}{s} = 0.4 \frac{(v - v_c)ud}{0.87 f_{\text{vy}}} \geq 0.4ud \frac{0.87 f_{\text{vy}}}{0.87 f_{\text{vy}}} \]  
  (BS 3.7.7.5)

- If \( 1.6v_c \leq v < 2.0v_c \),
  \[ \frac{A_v}{s} = 5 \frac{(0.7v - v_c)ud}{0.87 f_{\text{vy}}} \geq 0.4ud \frac{0.87 f_{\text{vy}}}{0.87 f_{\text{vy}}} \]  
  (BS 3.7.7.5)

- If \( v > v_{\text{max}} \), a failure condition is declared.  
  (BS 3.7.7.5)

If \( v \) exceeds the maximum permitted value of \( v_{\text{max}} \), the concrete section should be increased in size.

7.5.4.3 Determine Reinforcement Arrangement

Punching shear reinforcement in the vicinity of rectangular columns should be arranged on peripheral lines, i.e., lines running parallel to and at constant distances from the sides of the column. Figure 7-4 shows a typical arrangement of shear reinforcement in the vicinity of a rectangular interior, edge, and corner column.

The distance between the column face and the first line of shear reinforcement shall not exceed \( d/2 \). The spacing between adjacent shear reinforcement in the first line (perimeter) of shear reinforcement shall not exceed \( 1.5d \) measured in a direction parallel to the column face (BS 3.7.7.6).
Punching shear reinforcement is most effective near column corners where there are concentrations of shear stress. Therefore, the minimum number of lines of shear reinforcement is 4, 6, and 8, for corner, edge, and interior columns respectively.

7.5.4.4 Determine Reinforcement Diameter, Height, and Spacing

The punching shear reinforcement is most effective when the anchorage is close to the top and bottom surfaces of the slab. The cover of anchors should not be less than the minimum cover specified in BS 3.3 plus half of the diameter of the flexural reinforcement.

Punching shear reinforcement in the form of shear studs is generally available in 10-, 12-, 17-, 16-, and 20-millimeter diameters.

When specifying shear studs, the distance, \( s_o \), between the column face and the first peripheral line of shear studs should not be smaller than \( 0.5d \). The spacing between adjacent shear studs, \( g \), at the first peripheral line of studs shall not exceed \( 1.5d \). The limits of \( s_o \) and the spacing, \( s \), between the peripheral lines are specified as:

\[
s_o \leq 0.5d
\]

(BS 3.7.7.6)
\[ s \leq 0.75d \] (BS 3.7.7.6)
\[ g \leq 1.5d \] (BS 3.7.7.6)
Chapter 8
Design for CSA A23.3-14

This chapter describes in detail the various aspects of the concrete design procedure that is used by ETABS when the Canadian code CSA A23.3-14 [CSA 14] is selected. Various notations used in this chapter are listed in Table 5-1. For referencing to the pertinent sections of the Canadian code in this chapter, a prefix “CSA” followed by the section number is used.

The design is based on user-specified load combinations. The program provides a set of default load combinations that should satisfy the requirements for the design of most building type structures.

English as well as SI and MKS metric units can be used for input. The code is based on Newton-millimeter-second units. For simplicity, all equations and descriptions presented in this chapter correspond to Newton-millimeter-second units unless otherwise noted.

8.2 Design Load Combinations

The design load combinations are the various combinations of the load cases for which the structure needs to be designed. For CSA A23.3-14, if a structure is subjected to dead (D), live (L), pattern live (PL), snow (S), wind (W), and earthquake (E) loads, and considering that wind and earthquake forces are reversible, the following load combinations may need to be considered (CSA 8.3.2, Table C.1a)

1.4D
1.25D + 1.5L
1.25D + 1.5L + 1.0S
1.25D + 1.5L ± 0.4W
0.9D + 1.5L
0.9D + 1.5L + 1.0S
0.9D + 1.5L ± 0.4W

1.25D + 1.5(0.75 PL) (CSA 8.3.2, Table C.1a Case 1)
1.25D + 1.5S
1.25D + 1.5S + 0.5L
1.25D + 1.5S ± 0.4W
0.9D + 1.5S
0.9D + 1.5S + 0.5L
0.9D + 1.5S ± 0.4W

1.25D + 1.5L
1.25D + 1.5L + 1.0S
1.25D + 1.5L ± 0.4W

(CSA 8.3.2, Table C.1a Case 2)

1.25D + 1.5S
1.25D + 1.5S + 0.5L
1.25D + 1.5S ± 0.4W
0.9D + 1.5S
0.9D + 1.5S + 0.5L
0.9D + 1.5S ± 0.4W

(CSA 8.3.2, Table C.1a Case 3)
1.25D ± 1.4W
1.25D + 0.5L ± 1.4W
1.25D + 0.5S ± 1.4W
0.9D ± 1.4W
0.9D + 0.5L ± 1.4W
0.9D + 0.5S ± 1.4W

1.0D ± 1.0E
1.0D + 0.5L ± 1.0E
1.0D + 0.25S ± 1.0E
1.0D + 0.5L + 0.25S ± 1.0E

(CSA 8.3.2, Table C.1a Case 4)

These are also the default design load combinations in ETABS whenever the CSA A23.3-14 code is used. If roof live load is treated separately or other types of loads are present, other appropriate load combinations should be used.

### 8.3 Limits on Material Strength

The upper and lower limits of $f'_c$ are 80 MPa and 20 MPa, respectively, for all framing types (CSA 8.6.1.1).

$$20 \text{ MPa} \leq f'_c \leq 80 \text{ MPa}$$

(CSA 8.6.1.1)

The upper limit of $f_y$ is 500 MPa for all frames (CSA 8.5.1).

$$f_y \leq 500 \text{ MPa}$$

(CSA 8.5.1)

ETABS enforces the upper material strength limits for flexure and shear design of slabs. The input material strengths are taken as the upper limits if they are defined in the material properties as being greater than the limits. The user is responsible for ensuring that the minimum strength is satisfied.

### 8.4 Strength Reduction Factors

The strength reduction factors, $\phi$, are material dependent and defined as:

$$\phi_c = 0.65 \text{ for concrete}$$

(CSA 8.4.2)

$$\phi_s = 0.85 \text{ for reinforcement}$$

(CSA 8.4.3a)
These values can be overwritten; however, caution is advised.

8.5 Slab Design

ETABS slab design procedure involves defining sets of strips in two mutually perpendicular directions. The locations of the strips are usually governed by the locations of the slab supports. The axial force, moments and shears for a particular strip are recovered from the analysis (on the basis of the Wood-Armer technique), and a flexural design is carried out based on the ultimate strength design method.

The slab design procedure involves the following steps:

- Design flexural reinforcement
- Design shear reinforcement
- Punching check

8.5.1 Design Flexural Reinforcement

For slabs, ETABS uses either design strips or the finite element based design to calculate the slab flexural reinforcement in accordance with the selected design code. For simplicity, only strip-by-strip design is document in the proceeding sections.

The design of the slab reinforcement for a particular strip is carried out at specific locations along the length of the strip. These locations correspond to the element boundaries. Controlling reinforcement is computed on either side of those element boundaries. The slab flexural design procedure for each load combination involves the following:

- Determine factored axial loads and moments for each slab strip.
- Design flexural reinforcement for the strip.
- These two steps, described in the text that follows, are repeated for every load combination. The maximum reinforcement calculated for the top and bottom of the slab within each design strip, along with the corresponding controlling load combination, is obtained and reported.
8.5.1.1 Determine Factored Moments

In the design of flexural reinforcement of concrete slab, the factored moments for each load combination at a particular design strip are obtained by factoring the corresponding moments for different load cases, with the corresponding load factors.

The slab is then designed for the maximum positive and maximum negative factored moments obtained from all of the load combinations. Calculation of bottom reinforcement is based on positive design strip moments. In such cases, the slab may be designed as a rectangular or flanged slab section. Calculation of top reinforcement is based on negative design strip moments. In such cases, the slab may be designed as a rectangular or inverted flanged slab section.

8.5.1.2 Determine Required Flexural Reinforcement

In the flexural reinforcement design process, the program calculates both the tension and compression reinforcement. Compression reinforcement is added when the applied design moment exceeds the maximum moment capacity of a singly reinforced section. The user has the option of avoiding compression reinforcement by increasing the effective depth, the width, or the strength of the concrete.

The design procedure is based on the simplified rectangular stress block shown in Figure 8-1 (CSA 10.1.7). Furthermore, it is assumed that the compression carried by the concrete is less than or equal to that which can be carried at the balanced condition (CSA 10.1.4). When the applied moment exceeds the moment capacity at the balanced condition, the area of compression reinforcement is calculated assuming that the additional moment will be carried by compression and additional tension reinforcement.

The design procedure used by ETABS, for both rectangular and flanged sections (L- and T-shaped sections), is summarized in the text that follows. For reinforced concrete design where design ultimate axial compression load does not exceed \(0.1 f'c A_g\), axial force is ignored; hence, all slabs are designed for major direction flexure, shear, and punching shear only. Axial compression greater than \(0.1 f'c A_g\) and axial tensions are always included in flexural and shear design.
8.5.1.2.1 Design of uniform thickness slab

In designing for a factored negative or positive moment, \( M_f \) (i.e., designing top or bottom reinforcement), the depth of the compression block is given by \( a \) (see Figure 8-1), where,

\[
a = d - \sqrt{d^2 - \frac{2|M_f|}{\alpha_1 f'_c \phi_c b}}
\]  
(CSA 10.1)

where the value of \( \phi_c \) is 0.65 (CSA 8.4.2) in the preceding and the following equations. The parameters \( \alpha_1, \beta_1, \) and \( c_b \) are calculated as:

\[
\alpha_1 = 0.85 - 0.0015 f'_c \geq 0.67, 
\]  
(CSA 10.1.7)

\[
\beta_1 = 0.97 - 0.0025 f'_c \geq 0.67, 
\]  
(CSA 10.1.7)

\[
c_b = \frac{700}{700 + f_y} d 
\]  
(CSA 10.5.2)

Figure 8-1 Uniform Thickness Slab Design
The balanced depth of the compression block is given by:

\[ a_b = \beta_1 c_b \]  
(CSA 10.1.7)

- If \( a \leq a_b \) (CSA 10.5.2), the area of tension reinforcement is given by:

\[
A_t = \frac{M_f}{\phi_s f_y \left( d - \frac{a}{2} \right)}
\]

This reinforcement is to be placed at the bottom if \( M_f \) is positive, or at the top if \( M_f \) is negative.

- If \( a > a_b \) (CSA 10.5.2), compression reinforcement is required and is calculated as follows:

The factored compressive force developed in the concrete alone is given by:

\[ C = \phi_x \alpha_s f'_{y_c} b a_b \]  
(CSA 10.1.7)

and the factored moment resisted by concrete compression and tension reinforcement is:

\[ M_{fc} = C \left( d - \frac{a_b}{2} \right) \]

Therefore, the moment required to be resisted by compression reinforcement and tension reinforcement is:

\[ M_{fs} = M_f - M_{fc} \]

The required compression reinforcement is given by:

\[
A'_s = \frac{M_{fs}}{(\phi_s f'_{y_c} - \phi_x \alpha_s f'_{y_c})(d - d')} \]

where \( f'_{y_c} = 0.0035 E_s \left[ \frac{c - d'}{c} \right] \leq f_y \)  
(CSA 10.1.2, 10.1.3)
The required tension reinforcement for balancing the compression in the concrete is:

\[ A_{s1} = \frac{M_{fc}}{f_y \left( d - \frac{a_{b,c}}{2} \right) \phi_s} \]

and the tension reinforcement for balancing the compression reinforcement is given by:

\[ A_{s2} = \frac{M_{fs}}{f_y \left( d - d' \right) \phi_s} \]

Therefore, the total tension reinforcement, \( A_s = A_{s1} + A_{s2} \), and the total compression reinforcement is \( A'_s \). \( A_s \) is to be placed at the bottom and \( A'_s \) is to be placed at the top if \( M_f \) is positive, and vice versa if \( M_f \) is negative.

### 8.5.1.2.2 Design of nonuniform thickness slab

#### 8.5.1.2.2.1 Flanged Slab Section Under Negative Moment

In designing for a factored negative moment, \( M_f \) (i.e., designing top reinforcement), the calculation of the reinforcement area is exactly the same as described previously, i.e., no flanged data is used.

#### 8.5.1.2.2.2 Flanged Slab Section Under Positive Moment

- If \( M_f > 0 \), the depth of the compression block is given by:

\[ a = d - \sqrt{d^2 - \frac{2M_f}{\alpha_1 f'_c \phi_b b_f}} \quad \text{(CSA 10.1)} \]

where, the value of \( \phi_b \) is 0.65 (CSA 8.4.2) in the preceding and the following equations. The parameters \( \alpha_1, \beta_1, \) and \( c_b \) are calculated as:

\[ \alpha_1 = 0.85 - 0.0015 f'_c \geq 0.67, \quad \text{(CSA 10.1.7)} \]

\[ \beta_1 = 0.97 - 0.0025 f'_c \geq 0.67, \quad \text{(CSA 10.1.7)} \]
The balanced depth of the compression block is given by:

\[ a_b = \beta_1 c_b \]  

(CSA 10.1.4,10.1.7)

- If \( a \leq h_s \), the subsequent calculations for \( A_s \) are exactly the same as previously defined for the uniform thickness slab design. However, in this case the width of the slab is taken as \( b_f \). Compression reinforcement is required when \( a > a_b \).

- If \( a > h_s \), calculation for \( A_s \) has two parts. The first part is for balancing the compressive force from the flange, \( C_f \), and the second part is for balancing the compressive force from the web, \( C_w \) as shown in Figure 8-2. \( C_f \) is given by:

\[ C_f = \alpha_1 f' \left( b_f - b_w \right) \min(h_s, a_b) \]  

(CSA 10.1.7)

Therefore, \( A_{sl} = \frac{C_f \phi_c}{f_y \phi_s} \) and the portion of \( M_f \) that is resisted by the flange is given by:

**Figure 8-2 Nonuniform Thickness Slab Design**
Therefore, the balance of the moment, $M_f$ to be carried by the web is:

$$M_{fw} = M_f - M_{ff}$$

The web is a rectangular section with dimensions $b_w$ and $d$, for which the design depth of the compression block is recalculated as:

$$a_1 = d - \sqrt{d^2 - \frac{2M_{fw}}{\phi f_c a^* \phi c b_w}}$$

(CSA 10.1)

- If $a_1 \leq a_b$ (CSA 10.5.2), the area of tension reinforcement is then given by:

$$A_{s2} = \frac{M_{fw}}{\phi_b f_y d - a_1}$$

$$A_s = A_{s1} + A_{s2}$$

This reinforcement is to be placed at the bottom of the flanged slab.

- If $a_1 > a_b$ (CSA 10.5.2), compression reinforcement is required and is calculated as follows:

The compressive force in the web concrete alone is given by:

$$C = \phi c a_1 f_c^* b_w a_b$$

(CSA 10.1.7)

Therefore the moment resisted by the concrete web and tension reinforcement is:

$$M_{fc} = C \left( d - \frac{a_b}{2} \right)$$

and the moment resisted by compression and tension reinforcement is:

$$M_f = M_{fw} - M_{fc}$$
Therefore, the compression reinforcement is computed as:
\[
A'_c = \frac{M_{fs}}{(\phi f'_c - \phi_c f'_u)(d - d')} \quad \text{where}
\]
\[
f'_s = \varepsilon_c E_s \left[ \frac{c - d'}{c} \right] \leq f_y \quad \text{(CSA 10.1.2, 10.1.3)}
\]

The tension reinforcement for balancing compression in the web concrete is:
\[
A_{s2} = \frac{M_{fc}}{f'_y \left( d - \frac{a_b}{2} \right) \phi_s}
\]

and the tension reinforcement for balancing the compression reinforcement is:
\[
A_{s3} = \frac{M_{fs}}{f'_y (d - d') \phi_s}
\]

The total tension reinforcement is \( A_s = A_{s1} + A_{s2} + A_{s3} \), and the total compression reinforcement is \( A'_c \). \( A_s \) is to be placed at the bottom and \( A'_c \) is to be placed at the top.

### 8.5.1.3 Minimum and Maximum Reinforcement

The minimum flexural tensile reinforcement required for each direction of a slab is given by the following limit (CSA 13.10.1):
\[
A_v \geq 0.002 bh \quad \text{(CSA 7.8.1)}
\]

In addition, an upper limit on both the tension reinforcement and compression reinforcement has been imposed to be 0.04 times the gross cross-sectional area.

#### 8.5.2 Design Slab Shear Reinforcement

The shear reinforcement is designed for each load combination at each station along the design strip. In designing the shear reinforcement for a particular strip,
for a particular load combination, at a particular station due to the slab major shear, the following steps are involved:

- Determine the factored shear force, \( V_f \).
- Determine the shear force, \( V_c \), that can be resisted by the concrete.
- Determine the shear reinforcement required to carry the balance.

The following three subsections describe in detail the algorithms associated with these steps.

### 8.5.2.1 Determine Factored Shear Force

In the design of the slab shear reinforcement, the shear forces for each load combination at a particular design strip station are obtained by factoring the corresponding shear forces for different load cases, with the corresponding load combination factors.

### 8.5.2.2 Determine Concrete Shear Capacity

The shear force carried by the concrete, \( V_c \), is calculated as:

\[
V_c = \phi_c \lambda \beta \sqrt{f'_c b_w d_v}
\]  

(\text{CSA 11.3.4})

\[
\sqrt{f'_c} \leq 8 \text{ MPa}
\]  

(\text{CSA 11.3.4})

\( \phi_c \) is the resistance factor for concrete. By default it is taken as 0.65 (CSA 8.4.2).

\( \lambda \) is the strength reduction factor to account for low density concrete (CSA 2.2). For normal density concrete, its value is 1 (CSA 8.6.5), which is taken by the program as the default value. For concrete using lower density aggregate, the user can change the value of \( \lambda \) in the material property data. The recommended value for \( \lambda \) is as follows (CSA 8.6.5):
\[
\lambda = \begin{cases} 
1.00, & \text{for normal density concrete,} \\
0.85, & \text{for semi-low-density concrete in which all of the fine aggregate is natural sand,} \quad (\text{CSA 8.6.5}) \\
0.75, & \text{for semi-low-density concrete in which none of the fine aggregate is natural sand.} 
\end{cases}
\]

\(\beta\) is the factor for accounting for the shear resistance of cracked concrete (CSA 2.2) and should be greater or equal to 0.05. Its value is normally between 0.1 and 0.4. It is determined according to CSA 11.3.6, and described further in the following sections.

\(b_w\) is the effective web width. For uniform thickness slab, it is the width of the slab. For flanged-shaped slab, it is the width of the web of the slab.

\(d_v\) is the effective shear depth. It is taken as the greater of 0.9\(d\) or 0.72\(h\) (CSA 2.3), where \(d\) is the distance from the extreme compression fiber to the centroid of the tension reinforcement, and \(h\) is the overall depth of the cross-section in the direction of the shear force (CSA 2.3).

The value of \(\beta\) is preferably taken as the special value (CSA 11.3.6.2) or it is determined using the simplified method (CSA 11.3.6.3), if applicable. When the conditions of the special value or simplified method do not apply, the general method is used (CSA 11.3.6.4).

If the overall slab depth, \(h\), is less than 250 mm or if the depth of a flanged below the slab is not greater than one-half of the width of the web or 350 mm, \(\beta\) is taken as 0.21 (CSA 11.3.6.2).

When the specified yield strength of the longitudinal reinforcing \(f_y\) does not exceed 400 MPa, the specified concrete strength \(f'_c\) does not exceed 60 MPa, and the tensile force is negligible, \(\beta\) is determined in accordance with the simplified method, as follows (CSA 11.3.6.3):

- When the section contains at least the minimum transverse reinforcement, \(\beta\) is taken as 0.18 (CSA 11.6.3.3a).

\[
\beta = 0.18 
\]

(CSA 11.3.6.3(a))
When the section contains no transverse reinforcement, $\beta$ is determined based on the specified maximum nominal size of coarse aggregate, $a_g$.

For a maximum size of coarse aggregate not less than 20 mm, $\beta$ is taken as:

$$\beta = \frac{230}{1000 + d_v}$$

where $d_v$ is the effective shear depth expressed in millimeters.

For a maximum size of coarse aggregate less than 20 mm, $\beta$ is taken as:

$$\beta = \frac{230}{1000 + s_{ze}}$$

where, $s_{ze} = \frac{35s_z}{15 + a_g} \geq 0.85s_z$

In the preceding expression, the crack spacing parameter, $s_{ze}$, shall be taken as the minimum of $d_v$ and the maximum distance between layers of distributed longitudinal reinforcement. However, $s_{ze}$ is conservatively taken as equal to $d_v$.

In summary, for simplified cases, $\beta$ can be expressed as follows:

$$\beta = \begin{cases} 
0.18, & \text{if minimum transverse reinforcement is provided}, \\
\frac{230}{1000 + d_v}, & \text{if no transverse reinforcement is provided, and } a_g \geq 20\text{mm}, \\
\frac{230}{1000 + s_{ze}}, & \text{if no transverse reinforcement is provided, and } a_g < 20\text{mm}.
\end{cases}$$

When the specified yield strength of the longitudinal reinforcing $f_y$ is greater than 400 MPa, the specified concrete strength $f'_c$ is greater than 60 MPa, or tension is not negligible, $\beta$ is determined in accordance with the general method as follows (CSA 11.3.6.1, 11.3.6.4):

$$\beta = \frac{0.40}{(1+1500\varepsilon_{\varepsilon})} \cdot \frac{1300}{(1000 + S_{ze})}$$

(CSA 11.3.6.4)
In the preceding expression, the equivalent crack spacing parameter, $s_{ze}$ is taken equal to 300 mm if minimum transverse reinforcement is provided (CSA 11.3.6.4). Otherwise it is determined as stated in the simplified method.

$$
S_{ze} = \begin{cases} 
300 & \text{if minimum transverse reinforcement is provided,} \\
\frac{35}{15 + a_{g}}S_{z} \geq 0.85S_{z} & \text{otherwise.}
\end{cases}
$$

(CSA 11.3.6.3, 11.3.6.4)

The value of $a_{g}$ in the preceding equations is taken as the maximum aggregate size for $f'_{c}$ of 60 MPa, is taken as zero for $f'_{c}$ of 70 MPa, and linearly interpolated between these values (CSA 11.3.6.4).

The longitudinal strain, $\varepsilon_{x}$ at mid-depth of the cross-section is computed from the following equation:

$$\varepsilon_{x} = \frac{M_{f}/d_{v} + V_{f} + 0.5N_{f}}{2(E_{s}A_{s})}$$

(CSA 11.3.6.4)

In evaluating $\varepsilon_{x}$ the following conditions apply:

- $\varepsilon_{x}$ is positive for tensile action.
- $V_{f}$ and $M_{f}$ are taken as positive quantities. (CSA 11.3.6.4(a))
- $M_{f}$ is taken as a minimum of $V_{f}/d_{v}$. (CSA 11.3.6.4(a))
- $N_{f}$ is taken as positive for tension. (CSA 2.3)

$A_{s}$ is taken as the total area of longitudinal reinforcement in the slab. It is taken as the envelope of the reinforcement required for all design load combinations. The actual provided reinforcement might be slightly higher than this quantity. The reinforcement should be developed to achieve full strength (CSA 11.3.6.3(b)).

If the value of $\varepsilon_{x}$ is negative, it is recalculated with the following equation, in which $A_{cr}$ is the area of concrete in the flexural tensile side of the slab, taken as half of the total area.
ETABS Reinforced Concrete Design

\[ \varepsilon_x = \frac{M_f / d_v + V_f + 0.5N_f}{2(E_s A_s + E_c A_c)} \quad \text{(CSA 11.3.6.4(c))} \]

\[ E_s = 200,000 \text{ MPa} \quad \text{(CSA 8.5.4.1)} \]

\[ E_c = 4500 \sqrt{f_c'} \text{ MPa} \quad \text{(CSA 8.6.2.3)} \]

If the axial tension is large enough to induce tensile stress in the section, the value of \( \varepsilon_x \) is doubled (CSA 11.3.6.4(e)).

For sections closer than \( d_v \) from the face of the support, \( \varepsilon_x \) is calculated based on \( M_f \) and \( V_f \) at a section at a distance \( d_v \) from the face of the support (CSA 11.3.6.4(d)). This condition currently is not checked by ETABS.

An upper limit on \( \varepsilon_x \) is imposed as:

\[ \varepsilon_x \leq 0.003 \quad \text{(CSA 11.3.6.4(f))} \]

In both the simplified and general methods, the shear strength of the section due to concrete, \( v_c \), depends on whether the minimum transverse reinforcement is provided. To check this condition, the program performs the design in two passes. In the first pass, it assumes that no transverse shear reinforcement is needed. When the program determines that shear reinforcement is required, the program performs the second pass assuming that at least minimum shear reinforcement is provided.

**8.5.2.3 Determine Required Shear Reinforcement**

The shear force is limited to \( V_{r,\text{max}} \) where:

\[ V_{r,\text{max}} = 0.25 \phi_f f'\alpha b_w d \quad \text{(CSA 11.3.3)} \]

Given \( V_f, V_c, \) and \( V_{r,\text{max}} \), the required shear reinforcement is calculated as follows:

- If \( V_f \leq V_c \),

\[ \frac{A_v}{s} = 0 \quad \text{(CSA 11.3.5.1)} \]

8 - 18 Slab Design
- If \( V_{f} < V_{c} \leq V_{r,\text{max}} \),

\[
\frac{A_{v}}{s} = \frac{(V_{f} - V_{c})\tan \theta}{\phi_{c} f'_{y} d_{v}}
\]

(CSA 11.3.3, 11.3.5.1)

- If \( V_{f} > V_{r,\text{max}} \), a failure condition is declared. (CSA 11.3.3)

A minimum area of shear reinforcement is provided in the following regions (CSA 11.2.8.1):

(a) in regions of flexural members where the factored shear force \( V_{f} \) exceeds \( V_{c} \)

(b) in regions of slab with an overall depth greater than 750 mm.

Where the minimum shear reinforcement is required by CSA 11.2.8.1, or by calculation, the minimum area of shear reinforcement per unit spacing is taken as:

\[
\frac{A_{v}}{s} \geq 0.06 \sqrt{\frac{f'_{c}}{f_{y}}} b_{w}
\]

(CSA 11.2.8.2)

In the preceding equations, the term \( \theta \) is used, where \( \theta \) is the angle of inclination of the diagonal compressive stresses with respect to the longitudinal axis of the member (CSA 2.3). The \( \theta \) value is normally between 22 and 44 degrees. It is determined according to CSA 11.3.6.

Similar to the \( \beta \) factor, which was described previously, the value of \( \theta \) is preferably taken as the special value (CSA 11.3.6.2), or it is determined using the simplified method (CSA 11.3.6.3), whenever applicable. The program uses the general method when conditions for the simplified method are not satisfied (CSA 11.3.6.4).

- If the overall slab depth, \( h \), is less than 250 mm or if the depth of the flanged slab below the slab is not greater than one-half of the width of the web or 350 mm, \( \theta \) is taken as 42 degrees (CSA 11.3.6.2).

- If the specified yield strength of the longitudinal reinforcing \( f_{y} \) does not exceed 400 MPa, or the specified concrete strength \( f'_{c} \) does not exceed 60 MPa, \( \theta \) is taken to be 35 degree (CSA 11.3.6.3).
\[ \theta = 35^\circ \text{ for } P_f \leq 0 \text{ or } f_y \leq 400 \text{ MPa or } f'c \leq 60 \text{ MPa} \quad \text{(CSA11.3.6.3)} \]

- If the axial force is tensile, the specified yield strength of the longitudinal reinforcing \( f_y > 400 \text{ MPa}, \) and the specified concrete strength \( f'c > 60 \text{ MPa}, \) \( \theta \) is determined using the general method as follows (CSA 11.3.6.4),

\[ \theta = 29 + 7000\varepsilon_x \text{ for } P_f < 0, \ f_y > 400 \text{ MPa, } f'c \leq 60 \text{ MPa} \quad \text{(CSA11.3.6.4)} \]

where \( \varepsilon_x \) is the longitudinal strain at the mid-depth of the cross-section for the factored load. The calculation procedure is described in preceding sections.

The maximum of all of the calculated \( A_v/s \) values obtained from each load combination is reported along with the controlling shear force and associated load combination.

The slab shear reinforcement requirements considered by the program are based purely on shear strength considerations. Any minimum stirrup requirements to satisfy spacing and volumetric considerations must be investigated independently of the program by the user.

### 8.5.3 Check for Punching Shear

The algorithm for checking punching shear is detailed in the section entitled “Slab Punching Shear Check” in the Chapter 1. Only the code-specific items are described in the following sections.

#### 8.5.3.1 Critical Section for Punching Shear

The punching shear is checked on a critical section at a distance of \( d/2 \) from the face of the support (CSA 13.3.3.1 and CSA 13.3.3.2). For rectangular columns and concentrated loads, the critical area is taken as a rectangular area with the sides parallel to the sides of the columns or the point loads (CSA 13.3.3.3). Figure 8-3 shows the auto punching perimeters considered by ETABS for the various column shapes. The column location (i.e., interior, edge, corner) and the punching perimeter may be overwritten using the Punching Check Overwrites.
8.5.3.2 Transfer of Unbalanced Moment

The fraction of unbalanced moment transferred by flexure is taken to be $\gamma_f M_u$ and the fraction of unbalanced moment transferred by eccentricity of shear is taken to be $\gamma_v M_u$, where

$$\gamma_f = \frac{1}{1 + (2/3) \sqrt{b_1/b_2}} \quad \text{and} \quad (CSA \ 13.10.2)$$

$$\gamma_v = 1 - \frac{1}{1 + (2/3) \sqrt{b_1/b_2}} \quad \text{(CSA \ 13.3.5.3)}$$

where $b_1$ is the width of the critical section measured in the direction of the span, and $b_2$ is the width of the critical section measured in the direction perpendicular to the span.

8.5.3.3 Determination of Concrete Capacity

The concrete punching shear factored strength is taken as the minimum of the following three limits:
where, $\beta_c$ is the ratio of the minimum to the maximum dimensions of the critical section, $b_0$ is the perimeter of the critical section, and $\alpha_s$ is a scale factor based on the location of the critical section.

\[
\alpha_s = \begin{cases} 
4, & \text{for interior columns} \\
3, & \text{for edge columns, and} \\
2, & \text{for corner columns.} 
\end{cases} 
\] (CSA 13.3.4.1(b))

The value of $\sqrt{f_c'}$ is limited to 8 MPa for the calculation of the concrete shear capacity (CSA 13.3.4.2).

If the effective depth, $d$, exceeds 300 mm, the value of $v_c$ is reduced by a factor equal to $1300/(1000 + d)$ (CSA 13.4.3).

### 8.5.3.4 Determine Maximum Shear Stress

Given the punching shear force and the fractions of moments transferred by eccentricity of shear about the two axes, the shear stress is computed assuming linear variation along the perimeter of the critical section.

\[
v_f = \frac{V_f}{b_0 d} + \frac{\gamma_f(2M_{f2} - V_f(y_3 - y_1))}{I_{22}I_{33} - I_{23}^2} \left[ I_{33}(y_4 - y_3) - I_{23}(x_4 - x_3) \right] 
\]

\[
I_{22} = \sum_{sides = 1}^{n} I_{22}, \text{ where "sides" refers to the sides of the critical section for punching shear} 
\]

\[
Eq. 1
\]

\[
Eq. 2
\]
Chapter 8 - Design for CSA A23.3-14

\[ I_{33} = \sum_{sides=1}^{n} T_{33}, \]  where "sides" refers to the sides of the critical section for punching shear  

\[ I_{23} = \sum_{sides=1}^{n} T_{23}, \]  where "sides" refers to the sides of the critical section for punching shear

Eq. 3

Eq. 4

The equations for \( T_{22}, T_{33}, \) and \( T_{23} \) are different depending on whether the side of the critical section for punching shear being considered is parallel to the 2-axis or parallel to the 3-axis. Refer to Figures 8-4.

**Figure 8-4 Shear Stress Calculations at Critical Sections**
\[ T_{22} = Ld(y_2 - y_3)^2, \] for side of critical section parallel to 2-axis Eq. 5a

\[ T_{22} = \frac{Ld^3}{12} + \frac{dL^3}{12} + Ld(y_2 - y_3)^2, \] for side of critical section parallel to 3-axis Eq. 5b

\[ T_{33} = \frac{Ld^3}{12} + \frac{dL^3}{12} + Ld(x_2 - x_3)^2, \] for side of critical section parallel to 2-axis Eq. 6a

\[ T_{33} = Ld(x_2 - x_3)^2, \] for side of critical section parallel to 3-axis Eq. 6b

\[ T_{23} = Ld(x_2 - x_3)(y_2 - y_3), \] for side of critical section parallel to 2-axis or 3-axis Eq. 7

**NOTE:** \( T_{23} \) is explicitly set to zero for corner condition.

where,

- \( b_0 \) = Perimeter of the critical section for punching shear
- \( d \) = Effective depth at the critical section for punching shear based on the average of \( d \) for 2 direction and \( d \) for 3 direction
- \( I_{22} \) = Moment of inertia of the critical section for punching shear about an axis that is parallel to the local 2-axis
- \( I_{33} \) = Moment of inertia of the critical section for punching shear about an axis that is parallel to the local 3-axis
- \( I_{23} \) = Product of inertia of the critical section for punching shear with respect to the 2 and 3 planes
- \( L \) = Length of the side of the critical section for punching shear currently being considered
- \( M_{f2} \) = Moment about the line parallel to the 2-axis at the center of the column (positive in accordance with the right-hand rule)
\[ M_f = \text{Moment about the line parallel to the 3-axis at the center of the column (positive in accordance with the right-hand rule)} \]

\[ V_f = \text{Punching shear stress} \]

\[ V_f = \text{Shear at the center of the column (positive upward)} \]

\[ x_1, y_1 = \text{Coordinates of the column centroid} \]

\[ x_2, y_2 = \text{Coordinates of the center of one side of the critical section for punching shear} \]

\[ x_3, y_3 = \text{Coordinates of the centroid of the critical section for punching shear} \]

\[ x_4, y_4 = \text{Coordinates of the location where stress is being calculated} \]

\[ \gamma_2 = \text{Percent of } M_f \text{ resisted by shear} \]

\[ \gamma_3 = \text{Percent of } M_f \text{ resisted by shear} \]

**8.5.3.5 Determine Capacity Ratio**

The ratio of the maximum shear stress and the concrete punching shear stress capacity is reported as the punching shear capacity ratio by ETABS. If this ratio exceeds 1.0, punching shear reinforcement is designed as described in the following section.

**8.5.4 Design Punching Shear Reinforcement**

The use of shear studs as shear reinforcement in slabs is permitted, provided that the effective depth of the slab is greater than or equal to 200 mm (CSA 13.2.1). If the slab thickness does not meet these requirements, the punching shear reinforcement is not designed, and the slab thickness should be increased by the user.

The algorithm for designing the required punching shear reinforcement is used when the punching shear capacity ratio exceeds unity. The *Critical Section for Punching Shear and Transfer of Unbalanced Moment* as described in the earlier sections remain unchanged. The design of punching shear reinforcement is performed as explained in the subsections that follow.
8.5.4.1 Determine Concrete Shear Capacity

The concrete punching shear stress capacity of a section with punching shear reinforcement is taken as:

\[ v_c = 0.28 \lambda \phi_c \sqrt{f_{cb}} \] for shear studs \hspace{1cm} (CSA 13.3.8.3)

\[ v_c = 0.19 \lambda \phi_c \sqrt{f_{cb}} \] for shear stirrups \hspace{1cm} (CSA 13.3.9.3)

8.5.4.2 Determine Required Shear Reinforcement

The shear force is limited to a maximum of \( v_{r,\text{max}} \), where

\[ v_{r,\text{max}} = 0.75 \lambda \phi_c \sqrt{f_{cb}} \] for shear studs \hspace{1cm} (CSA 13.3.8.2)

\[ v_{r,\text{max}} = 0.55 \lambda \phi_c \sqrt{f_{cb}} \] for shear stirrups \hspace{1cm} (CSA 13.3.9.2)

Given \( v_f \), \( v_c \), and \( v_{r,\text{max}} \), the required shear reinforcement is calculated as follows, where, \( \phi_s \), is the strength reduction factor.

- If \( v_f > v_{r,\text{max}} \),

\[ A_s = \left( \frac{v_f - v_c}{\phi_s f_{yv}} \right) b_o \] \hspace{1cm} (CSA 13.3.8.5, 13.3.9.4)

- If \( v_f > v_{r,\text{max}} \), a failure condition is declared. \hspace{1cm} (CSA 13.3.8.2)

- If \( v_f \) exceeds the maximum permitted value of \( v_{r,\text{max}} \), the concrete section should be increased in size.

8.5.4.3 Determine Reinforcement Arrangement

Punching shear reinforcement in the vicinity of rectangular columns should be arranged on peripheral lines, i.e., lines running parallel to and at constant distances from the sides of the column. Figure 8-5 shows a typical arrangement of shear reinforcement in the vicinity of a rectangular interior, edge, and corner column.
The distance between the column face and the first line of shear reinforcement shall not exceed

\[ 0.4d \text{ for shear studs} \]  
\[ 0.25d \text{ for shear stirrups} \]  

(CSA 13.3.8.6)

Punching shear reinforcement is most effective near column corners where there are concentrations of shear stress. Therefore, the minimum number of lines of shear reinforcement is 4, 6, and 8, for corner, edge, and interior columns respectively.

### 8.5.4.4 Determine Reinforcement Diameter, Height, and Spacing

The punching shear reinforcement is most effective when the anchorage is close to the top and bottom surfaces of the slab. The cover of anchors should not be less than the minimum cover specified in CSA 7.9 plus half of the diameter of the flexural reinforcement.

When specifying shear studs, the distance, \( s_o \), between the column face and the first peripheral line of shear studs should not be smaller than \( 0.45d \) to \( 0.4d \). The limits of \( s_o \) and the spacing, \( s \), between the peripheral lines are specified as:

\[ s_o \leq 0.4d \]  

(CSA 13.3.8.6)
ETABS Reinforced Concrete Design

\[
s \begin{cases} 
0.75d & v_f \leq 0.56\lambda\phi_c\sqrt{f'_c} \\
0.50d & v_f > 0.56\lambda\phi_c\sqrt{f'_c}
\end{cases}
\]  
(CSA 13.3.8.6)

For shear stirrups,

\[
s_o \leq 0.25d 
\]  
(CSA 13.3.9.5)

\[
s \leq 0.25d 
\]  
(CSA 13.3.9.5)

The minimum depth for reinforcement should be limited to 300 mm (CSA 13.3.9.1).
Chapter 9
Design for CSA A23.3-04

This chapter describes in detail the various aspects of the concrete design procedure that is used by ETABS when the Canadian code CSA A23.3-04 [CSA 04] is selected. Various notations used in this chapter are listed in Table 9-1. For referencing to the pertinent sections of the Canadian code in this chapter, a prefix “CSA” followed by the section number is used.

The design is based on user-specified load combinations. The program provides a set of default load combinations that should satisfy the requirements for the design of most building type structures.

English as well as SI and MKS metric units can be used for input. The code is based on Newton-millimeter-second units. For simplicity, all equations and descriptions presented in this chapter correspond to Newton-millimeter-second units unless otherwise noted.

The design load combinations are the various combinations of the load cases for which the structure needs to be designed. For CSA A23.3-04, if a structure is subjected to dead (D), live (L), pattern live (PL), snow (S), wind (W), and earthquake (E) loads, and considering that wind and earthquake forces are reversible, the following load combinations may need to be considered (CSA 8.3.2, Table C.1)

1.4D
1.25D + 1.5L
1.25D + 1.5L + 0.5S

These are also the default design load combinations in ETABS whenever the
CSA A23.3-04 code is used. If roof live load is treated separately or other types
of loads are present, other appropriate load combinations should be used.

9.3 Limits on Material Strength

The upper and lower limits of $f'_{c}$ are 80 MPa and 20 MPa, respectively, for all
framing types (CSA 8.6.1.1).

$$20 \text{ MPa} \leq f'_{c} \leq 80 \text{ MPa}$$

The upper limit of $f_{y}$ is 500 MPa for all frames (CSA 8.5.1).

$$f_{y} \leq 500 \text{ MPa}$$

ETABS enforces the upper material strength limits for flexure and shear design
slabs. The input material strengths are taken as the upper limits if they are de-
finite in the material properties as being greater than the limits. The user is re-
sponsible for ensuring that the minimum strength is satisfied.

9.4 Strength Reduction Factors

The strength reduction factors, $\phi$, are material dependent and defined as:

$$\phi_{c} = 0.65 \text{ for concrete}$$

$$\phi_{s} = 0.85 \text{ for reinforcement}$$
These values can be overwritten; however, caution is advised.

9.5 Slab Design

ETABS slab design procedure involves defining sets of strips in two mutually perpendicular directions. The locations of the strips are usually governed by the locations of the slab supports. The axial force, moments and shears for a particular strip are recovered from the analysis (on the basis of the Wood-Armer technique), and a flexural design is carried out based on the ultimate strength design method.

The slab design procedure involves the following steps:

- Design flexural reinforcement
- Design shear reinforcement
- Punching check

9.5.1 Design Flexural Reinforcement

For slabs, ETABS uses either design strips or the finite element based design to calculate the slab flexural reinforcement in accordance with the selected design code. For simplicity, only strip-by-strip design is document in the proceeding sections.

The design of the slab reinforcement for a particular strip is carried out at specific locations along the length of the strip. These locations correspond to the element boundaries. Controlling reinforcement is computed on either side of those element boundaries. The slab flexural design procedure for each load combination involves the following:

- Determine factored axial loads and moments for each slab strip.
- Design flexural reinforcement for the strip.
- These two steps, described in the text that follows, are repeated for every load combination. The maximum reinforcement calculated for the top and bottom of the slab within each design strip, along with the corresponding controlling load combination, is obtained and reported.
9.5.1.1 Determine Factored Moments

In the design of flexural reinforcement of concrete slab, the factored moments for each load combination at a particular design strip are obtained by factoring the corresponding moments for different load cases, with the corresponding load factors.

The slab is then designed for the maximum positive and maximum negative factored moments obtained from all of the load combinations. Calculation of bottom reinforcement is based on positive design strip moments. In such cases, the slab may be designed as a rectangular or flanged slab section. Calculation of top reinforcement is based on negative design strip moments. In such cases, the slab may be designed as a rectangular or inverted flanged slab section.

9.5.1.2 Determine Required Flexural Reinforcement

In the flexural reinforcement design process, the program calculates both the tension and compression reinforcement. Compression reinforcement is added when the applied design moment exceeds the maximum moment capacity of a singly reinforced section. The user has the option of avoiding compression reinforcement by increasing the effective depth, the width, or the strength of the concrete.

The design procedure is based on the simplified rectangular stress block shown in Figure 9-1 (CSA 10.1.7). Furthermore, it is assumed that the compression carried by the concrete is less than or equal to that which can be carried at the balanced condition (CSA 10.1.4). When the applied moment exceeds the moment capacity at the balanced condition, the area of compression reinforcement is calculated assuming that the additional moment will be carried by compression and additional tension reinforcement.

The design procedure used by ETABS, for both rectangular and flanged sections (L- and T-shaped sections), is summarized in the text that follows. For reinforced concrete design where design ultimate axial compression load does not exceed \(0.1 f' c \cdot A_g\), axial force is ignored; hence, all slabs are designed for major direction flexure, shear, and torsion only. Axial compression greater than \(0.1 f' c \cdot A_g\) and axial tensions are always included in flexural and shear design.
9.5.1.2.1  Design of uniform thickness slab

In designing for a factored negative or positive moment, $M_f$ (i.e., designing top or bottom reinforcement), the depth of the compression block is given by $a$ (see Figure 9-1), where,

$$ a = d - \sqrt{d^2 - \frac{2|M_f|}{\alpha_1 f'_c \phi_c b}} $$

where the value of $\phi_c$ is 0.65 (CSA 8.4.2) in the preceding and the following equations. The parameters $\alpha_i$, $\beta_i$, and $c_b$ are calculated as:

$$ \alpha_i = 0.85 - 0.0015 f'_c \geq 0.67, \quad \text{(CSA 10.1.7)} $$

$$ \beta_i = 0.97 - 0.0025 f'_c \geq 0.67, \quad \text{(CSA 10.1.7)} $$

$$ c_b = \frac{700}{700 + f_y} d \quad \text{(CSA 10.5.2)} $$

$\beta_1$

$\varepsilon_s$

$T_\varepsilon$

$T_s$

$CSA 10.1$
The balanced depth of the compression block is given by:

\[ a_b = \beta_1 c_b \quad \text{(CSA 10.1.7)} \]

- If \( a \leq a_b \) (CSA 10.5.2), the area of tension reinforcement is given by:

\[
A_s = \frac{M_f}{\phi_s f_y \left( d - \frac{a}{2} \right)}
\]

This reinforcement is to be placed at the bottom if \( M_f \) is positive, or at the top if \( M_f \) is negative.

- If \( a > a_b \) (CSA 10.5.2), compression reinforcement is required and is calculated as follows:

The factored compressive force developed in the concrete alone is given by:

\[
C = \phi_c \alpha_s f_y' c_b a_b \quad \text{(CSA 10.1.7)}
\]

and the factored moment resisted by concrete compression and tension reinforcement is:

\[
M_{fc} = C \left( d - \frac{a_b}{2} \right)
\]

Therefore, the moment required to be resisted by compression reinforcement and tension reinforcement is:

\[
M_{fs} = M_f - M_{fc}
\]

The required compression reinforcement is given by:

\[
A_{s'} = \frac{M_{fs}}{(\phi_s f_y' - \phi_c \alpha_s f_y')(d - d')} \quad \text{where}
\]

\[
f_y' = 0.0035 E_s \left[ \frac{c - d''}{c} \right] \leq f_y \quad \text{(CSA 10.1.2, 10.1.3)}
\]
The required tension reinforcement for balancing the compression in the concrete is:

\[ A_{s1} = \frac{M_{fc}}{f_y \left( d - \frac{a_{fb}}{2} \right) \phi_s} \]

and the tension reinforcement for balancing the compression reinforcement is given by:

\[ A_{s2} = \frac{M_{fs}}{f_y (d - d') \phi_s} \]

Therefore, the total tension reinforcement, \( A_s = A_{s1} + A_{s2} \), and the total compression reinforcement is \( A'_s \). \( A_s \) is to be placed at the bottom and \( A'_s \) is to be placed at the top if \( M_f \) is positive, and vice versa if \( M_f \) is negative.

9.5.1.2.2 Design of nonuniform thickness slab

9.5.1.2.2.1 Flanged Slab Section Under Negative Moment

In designing for a factored negative moment, \( M_f \) (i.e., designing top reinforcement), the calculation of the reinforcement area is exactly the same as described previously, i.e., no flanged data is used.

9.5.1.2.2.2 Flanged Slab Section Under Positive Moment

- If \( M_f > 0 \), the depth of the compression block is given by:

\[ a = d - \sqrt{\frac{d^2 - \frac{2M_f}{\alpha_1 f'_c \phi_b b_f}}{\alpha_i f'_c \phi_c}} \]  

(CSA 10.1)

where, the value of \( \phi_c \) is 0.65 (CSA 8.4.2) in the preceding and the following equations. The parameters \( \alpha_i, \beta_i, \) and \( c_b \) are calculated as:

\[ \alpha_i = 0.85 - 0.0015 f'_c \geq 0.67, \]  

(CSA 10.1.7)

\[ \beta_i = 0.97 - 0.0025 f'_c \geq 0.67, \]  

(CSA 10.1.7)
The balanced depth of the compression block is given by:

\[ a_b = \beta_1 c_b \]  

(CSA 10.1.4,10.1.7)

- If \( a \leq h_s \), the subsequent calculations for \( A_s \) are exactly the same as previously defined for the uniform thickness slab design. However, in this case the width of the slab is taken as \( b_f \). Compression reinforcement is required when \( a > a_b \).

- If \( a > h_s \), calculation for \( A_s \) has two parts. The first part is for balancing the compressive force from the flange, \( C_f \), and the second part is for balancing the compressive force from the web, \( C_w \) as shown in Figure 9-2. \( C_f \) is given by:

\[ C_f = \alpha_1 f_c \left(b_f - b_w\right) \min(h_s, a_b) \]  

(CSA 10.1.7)

Therefore, \( A_{sl} = \frac{C_f \phi}{f_y \phi_s} \) and the portion of \( M_f \) that is resisted by the flange is given by:
Therefore, the balance of the moment, \( M_f \) to be carried by the web is:

\[
M_{fw} = M_f - M_{ff}
\]

The web is a rectangular section with dimensions \( b_w \) and \( d \), for which the design depth of the compression block is recalculated as:

\[
a_1 = d - \sqrt{d^2 - \frac{2M_{fw}}{\alpha_1 f'_c \phi_c b_w}}
\]

(CSA 10.1)

- If \( a_1 \leq a_b \) (CSA 10.5.2), the area of tension reinforcement is then given by:

\[
A_{s2} = \frac{M_{fw}}{\phi_s f_y \left( d - \frac{a_1}{2} \right)}, \text{ and}
\]

\[
A_s = A_{s1} + A_{s2}
\]

This reinforcement is to be placed at the bottom of the flanged slab.

- If \( a_1 > a_b \) (CSA 10.5.2), compression reinforcement is required and is calculated as follows:

The compressive force in the web concrete alone is given by:

\[
C = \phi_c \alpha_1 f'_c b_w a_b
\]

(CSA 10.1.7)

Therefore the moment resisted by the concrete web and tension reinforcement is:

\[
M_{fc} = C \left( d - \frac{a_b}{2} \right)
\]

and the moment resisted by compression and tension reinforcement is:

\[
M_{fc} = M_{fw} - M_{fc}
\]
Therefore, the compression reinforcement is computed as:

\[ A_s' = \frac{M_{fs}}{(\phi f_s' - \phi_a f_a') (d - d')} \],

where

\[ f_s' = \varepsilon_c E_s \left[ \frac{c - d'}{c} \right] \leq f_y \] (CSA 10.1.2, 10.1.3)

The tension reinforcement for balancing compression in the web concrete is:

\[ A_{s2} = \frac{M_{fc}}{f_y (d - a_h) \phi_s} \]

and the tension reinforcement for balancing the compression reinforcement is:

\[ A_{s3} = \frac{M_{fs}}{f_y (d - d') \phi_s} \]

The total tension reinforcement is \( A_s = A_{s1} + A_{s2} + A_{s3} \), and the total compression reinforcement is \( A'_s \). \( A_s \) is to be placed at the bottom and \( A'_s \) is to be placed at the top.

### 9.5.1.3 Minimum and Maximum Reinforcement

The minimum flexural tensile reinforcement required for each direction of a slab is given by the following limit (CSA 13.10.1):

\[ A_s \geq 0.002 \, bh \] (CSA 7.8.1)

- In addition, an upper limit on both the tension reinforcement and compression reinforcement has been imposed to be 0.04 times the gross cross-sectional area.

### 9.5.2 Design Slab Shear Reinforcement

The shear reinforcement is designed for each load combination at each station along the design strip. In designing the shear reinforcement for a particular strip,
ETABS Reinforced Concrete Design

for a particular load combination, at a particular station due to the slab major shear, the following steps are involved:

- Determine the factored shear force, $V_f$.
- Determine the shear force, $V_c$, that can be resisted by the concrete.
- Determine the shear reinforcement required to carry the balance.

The following three subsections describe in detail the algorithms associated with these steps.

### 9.5.2.1 Determine Concrete Shear Capacity

The shear force carried by the concrete, $V_c$, is calculated as:

$$ V_c = \phi_c \lambda \beta \sqrt{f'_c} b_w d_v $$

(CSA 11.3.4)

$$ \sqrt{f'_c} \leq 8 \text{ MPa} $$

(CSA 11.3.4)

$\phi_c$ is the resistance factor for concrete. By default it is taken as 0.65 (CSA 8.4.2).

$\lambda$ is the strength reduction factor to account for low density concrete (CSA 2.2). For normal density concrete, its value is 1 (CSA 8.6.5), which is taken by the program as the default value. For concrete using lower density aggregate, the user can change the value of $\lambda$ in the material property data. The recommended value for $\lambda$ is as follows (CSA 8.6.5):

$$ \lambda = \begin{cases} 
1.00, & \text{for normal density concrete,} \\
0.85, & \text{for semi-low-density concrete}
\end{cases} $$

(CSA 8.6.5)

in which all of the fine aggregate is natural sand.

$$ \lambda = \begin{cases} 
0.75, & \text{for semi-low-density concrete} \\
\text{in which none of the fine aggregate is natural sand.}
\end{cases} $$

$\beta$ is the factor for accounting for the shear resistance of cracked concrete (CSA 2.2). Its value is normally between 0.1 and 0.4. It is determined according to CSA 11.3.6, and described further in the following sections.
$b_w$ is the effective web width. For uniform thickness slab, it is the width of the slab. For flanged-shaped slab, it is the width of the web of the slab.

$d_v$ is the effective shear depth. It is taken as the greater of 0.9$d$ or 0.72$h$ (CSA 2.3), where $d$ is the distance from the extreme compression fiber to the centroid of the tension reinforcement, and $h$ is the overall depth of the cross-section in the direction of the shear force (CSA 2.3).

The value of $\beta$ is preferably taken as the special value (CSA 11.3.6.2) or it is determined using the simplified method (CSA 11.3.6.3), if applicable. When the conditions of the special value or simplified method do not apply, the general method is used (CSA 11.3.6.4).

If the overall slab depth, $h_r$, is less than 250 mm or if the depth of a flanged below the slab is not greater than one-half of the width of the web or 350 mm, $\beta$ is taken as 0.21 (CSA 11.3.6.2).

When the specified yield strength of the longitudinal reinforcing $f_y$ does not exceed 400 MPa, the specified concrete strength $f'_c$ does not exceed 60 MPa, and the tensile force is negligible, $\beta$ is determined in accordance with the simplified method, as follows (CSA 11.3.6.3):

- When the section contains at least the minimum transverse reinforcement, $\beta$ is taken as 0.18 (CSA 11.6.3.3a).
  
  \[
  \beta = 0.18 \quad \text{(CSA 11.3.6.3(a))}
  \]

- When the section contains no transverse reinforcement, $\beta$ is determined based on the specified maximum nominal size of coarse aggregate, $a_g$.

For a maximum size of coarse aggregate not less than 20 mm, $\beta$ is taken as:

\[
\beta = \frac{230}{1000 + d_v} \quad \text{(CSA 11.3.6.3(b))}
\]

where $d_v$ is the effective shear depth expressed in millimeters.

For a maximum size of coarse aggregate less than 20 mm, $\beta$ is taken as:

\[
\beta = \frac{230}{1000 + s_{cr}} \quad \text{(CSA 11.3.6.3 c)}
\]
where, \( s_{ze} = \frac{35s_z}{15 + a_g} \geq 0.85s_z \)  

(CSA 11.3.6.3.c)

In the preceding expression, the crack spacing parameter, \( s_{ze} \), shall be taken as the minimum of \( d_v \) and the maximum distance between layers of distributed longitudinal reinforcement. However, \( s_{ze} \) is conservatively taken as equal to \( d_v \).

In summary, for simplified cases, \( \beta \) can be expressed as follows:

\[
\beta = \begin{cases} 
0.18, & \text{if minimum transverse reinforcement is provided}, \\
230, & \text{if no transverse reinforcement is provided, and } a_g \geq 20\text{mm}, \\
\frac{230}{1000 + d_v}, & \text{if no transverse reinforcement is provided, and } a_g < 20\text{mm}.
\end{cases}
\]

- When the specified yield strength of the longitudinal reinforcing \( f_y \) is greater than 400 MPa, the specified concrete strength \( f'_{c} \) is greater than 60 MPa, or tension is not negligible, \( \beta \) is determined in accordance with the general method as follows (CSA 11.3.6.1, 11.3.6.4):

\[
\beta = \frac{0.40}{1 + 1500S_{ze}} \cdot \frac{1300}{1000 + S'_{ze}}
\]

(CSA 11.3.6.4)

In the preceding expression, the equivalent crack spacing parameter, \( s_{ze} \), is taken equal to 300 mm if minimum transverse reinforcement is provided (CSA 11.3.6.4). Otherwise it is determined as stated in the simplified method.

\[
S'_{ze} = \begin{cases} 
300, & \text{if minimum transverse reinforcement is provided}, \\
\frac{35}{15 + a_g}S_z \geq 0.85S_z, & \text{otherwise}.
\end{cases}
\]

(CSA 11.3.6.3, 11.3.6.4)

The value of \( a_g \) in the preceding equations is taken as the maximum aggregate size for \( f'_{c} \) of 60 MPa, is taken as zero for \( f'_{c} \) of 70 MPa, and linearly interpolated between these values (CSA 11.3.6.4).
Chapter 9 - Design for CSA A23.3-04

The longitudinal strain, $\varepsilon_x$ at mid-depth of the cross-section is computed from the following equation:

$$
\varepsilon_x = \frac{M_f/d_v + V_f + 0.5N_f}{2(E_s A_s)}
$$

(CSA 11.3.6.4)

In evaluating $\varepsilon_x$ the following conditions apply:

- $\varepsilon_x$ is positive for tensile action.
- $V_f$ and $M_f$ are taken as positive quantities. (CSA 11.3.6.4(a))
- $M_f$ is taken as a minimum of $V_f d_v$. (CSA 11.3.6.4(a))
- $N_f$ is taken as positive for tension. (CSA 2.3)

$A_s$ is taken as the total area of longitudinal reinforcement in the slab. It is taken as the envelope of the reinforcement required for all design load combinations. The actual provided reinforcement might be slightly higher than this quantity. The reinforcement should be developed to achieve full strength (CSA 11.3.6.3(b)).

If the value of $\varepsilon_x$ is negative, it is recalculated with the following equation, in which $A_{ct}$ is the area of concrete in the flexural tensile side of the slab, taken as half of the total area.

$$
\varepsilon_x = \frac{M_f/d_v + V_f + 0.5N_f}{2(E_s A_s + E_c A_{ct})}
$$

(CSA 11.3.6.4(c))

$E_s = 200,000$ MPa

(CSA 8.5.4.1)

$E_c = 4500\sqrt{f'_c}$ MPa

(CSA 8.6.2.3)

If the axial tension is large enough to induce tensile stress in the section, the value of $\varepsilon_x$ is doubled (CSA 11.3.6.4(c)).

For sections closer than $d_v$ from the face of the support, $\varepsilon_x$ is calculated based on $M_f$ and $V_f$ at a section at a distance $d_v$ from the face of the support (CSA 11.3.6.4(d)). This condition currently is not checked by ETABS.
An upper limit on $\varepsilon_x$ is imposed as:

$$\varepsilon_x \leq 0.003 \quad \text{(CSA 11.3.6.4(f))}$$

In both the simplified and general methods, the shear strength of the section due to concrete, $v_c$, depends on whether the minimum transverse reinforcement is provided. To check this condition, the program performs the design in two passes. In the first pass, it assumes that no transverse shear reinforcement is needed. When the program determines that shear reinforcement is required, the program performs the second pass assuming that at least minimum shear reinforcement is provided.

### 9.5.2.2 Determine Required Shear Reinforcement

The shear force is limited to $V_{r,\text{max}}$ where:

$$V_{r,\text{max}} = 0.25\phi^f_c f_c' b_w d$$ \quad \text{(CSA 11.3.3)}

Given $V_f$, $V_c$, and $V_{r,\text{max}}$, the required shear reinforcement is calculated as follows:

- If $V_f \leq V_c$,
  $$\frac{A_s}{s} = 0 \quad \text{(CSA 11.3.5.1)}$$

- If $V_c < V_f \leq V_{r,\text{max}}$,
  $$\frac{A_s}{s} = \frac{(V_f - V_c)\tan \theta}{\phi^f_c f_c' d_v} \quad \text{(CSA 11.3.3, 11.3.5.1)}$$

- If $V_f > V_{r,\text{max}}$, a failure condition is declared. \quad \text{(CSA 11.3.3)}

A minimum area of shear reinforcement is provided in the following regions (CSA 11.2.8.1):

(a) in regions of flexural members where the factored shear force $V_f$ exceeds $V_c$

(b) in regions of slab with an overall depth greater than 750 mm.
Where the minimum shear reinforcement is required by CSA 11.2.8.1, or by calculation, the minimum area of shear reinforcement per unit spacing is taken as:

\[
\frac{A_v}{s} \geq 0.06 \frac{f'_c}{f_{yw}} b_w
\]  

(CSA 11.2.8.2)

In the preceding equations, the term \( \theta \) is used, where \( \theta \) is the angle of inclination of the diagonal compressive stresses with respect to the longitudinal axis of the member (CSA 2.3). The \( \theta \) value is normally between 22 and 44 degrees. It is determined according to CSA 11.3.6.

Similar to the \( \beta \) factor, which was described previously, the value of \( \theta \) is preferably taken as the special value (CSA 11.3.6.2), or it is determined using the simplified method (CSA 11.3.6.3), whenever applicable. The program uses the general method when conditions for the simplified method are not satisfied (CSA 11.3.6.4).

- If the overall slab depth, \( h \), is less than 250 mm or if the depth of the flanged slab below the slab is not greater than one-half of the width of the web or 350 mm, \( \theta \) is taken as 42 degrees (CSA 11.3.6.2).

- If the specified yield strength of the longitudinal reinforcing \( f_y \) does not exceed 400 MPa, or the specified concrete strength \( f'_c \) does not exceed 60 MPa, \( \theta \) is taken to be 35 degree (CSA 11.3.6.3).

\[
\theta = 35^\circ \text{ for } P_f \leq 0 \text{ or } f_y \leq 400 \text{ MPa or } f'_c \leq 60 \text{ MPa}  \quad \text{(CSA11.3.6.3)}
\]

- If the axial force is tensile, the specified yield strength of the longitudinal reinforcing \( f_y > 400 \) MPa, and the specified concrete strength \( f'_c > 60 \) MPa, \( \theta \) is determined using the general method as follows (CSA 11.3.6.4),

\[
\theta = 29 + 7000\varepsilon_x \text{ for } P_f < 0, \; f_y > 400 \text{ MPa, } f'_c \leq 60 \text{ MPa}  \quad \text{(CSA11.3.6.4)}
\]

where \( \varepsilon_x \) is the longitudinal strain at the mid-depth of the cross-section for the factored load. The calculation procedure is described in preceding sections.

The maximum of all of the calculated \( A_v/s \) values obtained from each load combination is reported along with the controlling shear force and associated load combination.
The slab shear reinforcement requirements considered by the program are based purely on shear strength considerations. Any minimum stirrup requirements to satisfy spacing and volumetric considerations must be investigated independently of the program by the user.

9.5.3 Check for Punching Shear

The algorithm for checking punching shear is detailed in the section entitled “Slab Punching Shear Check” in the Chapter 1. Only the code-specific items are described in the following sections.

9.5.3.1 Critical Section for Punching Shear

The punching shear is checked on a critical section at a distance of \( d/2 \) from the face of the support (CSA 13.3.3.1 and CSA 13.3.3.2). For rectangular columns and concentrated loads, the critical area is taken as a rectangular area with the sides parallel to the sides of the columns or the point loads (CSA 13.3.3.3). Figure 9-3 shows the auto punching perimeters considered by ETABS for the various column shapes. The column location (i.e., interior, edge, corner) and the punching perimeter may be overwritten using the Punching Check Overwrites.

![Figure 9-3 Punching Shear Perimeters](image-url)
9.5.3.2 Transfer of Unbalanced Moment

The fraction of unbalanced moment transferred by flexure is taken to be \( \gamma_f M_u \) and the fraction of unbalanced moment transferred by eccentricity of shear is taken to be \( \gamma_v M_u \), where

\[
\gamma_f = \frac{1}{1 + \left(\frac{2}{3}\right) \sqrt{b_1/b_2}}, \quad \text{and} \quad \text{(CSA 13.10.2)}
\]
\[
\gamma_v = 1 - \frac{1}{1 + \left(\frac{2}{3}\right) \sqrt{b_1/b_2}}, \quad \text{where} \quad \text{(CSA 13.3.5.3)}
\]

where \( b_1 \) is the width of the critical section measured in the direction of the span, and \( b_2 \) is the width of the critical section measured in the direction perpendicular to the span.

9.5.3.3 Determination of Concrete Capacity

The concrete punching shear factored strength is taken as the minimum of the following three limits:

\[
v_c = \min \left\{ \phi_f \left( 1 + \frac{2}{\beta_c} \right) 0.19 \lambda \sqrt{f'_{cc}} \right. \\
\phi_c \left( 0.19 + \frac{\alpha_s d}{b_0} \right) 2 \sqrt{f'_{cc}} \right. \\
\phi_c 0.38 \lambda \sqrt{f'_{cc}} \right\} \quad \text{(CSA 13.3.4.1)}
\]

where, \( \beta_c \) is the ratio of the minimum to the maximum dimensions of the critical section, \( b_0 \) is the perimeter of the critical section, and \( \alpha_s \) is a scale factor based on the location of the critical section.

\[
\alpha_s = \begin{cases} 
4, & \text{for interior columns} \\
3, & \text{for edge columns, and} \\
2, & \text{for corner columns.} 
\end{cases} \quad \text{(CSA 13.3.4.1(b))}
\]
The value of \( \sqrt{f'c} \) is limited to 8 MPa for the calculation of the concrete shear capacity (CSA 13.3.4.2).

If the effective depth, \( d \), exceeds 300 mm, the value of \( v_c \) is reduced by a factor equal to \( 1300/(1000 + d) \) (CSA 13.3.4.3).

9.5.3.4 Determine Maximum Shear Stress

Given the punching shear force and the fractions of moments transferred by eccentricity of shear about the two axes, the shear stress is computed assuming linear variation along the perimeter of the critical section.

\[
\gamma_f = \frac{V_f}{b_d} + \gamma_{v2}\left[2I_{22} - V_f(y_3 - y_1)\right]\frac{I_{33}y_2}{I_{22}I_{33} - I_{23}^2} - \gamma_{v3}\left[2I_{13} - V_f(x_3 - x_1)\right]\frac{I_{22}y_3}{I_{22}I_{33} - I_{23}^2}
\]

Eq. 1

\[
I_{22} = \sum_{sides = 1}^{n} I_{22}, \text{ where "sides" refers to the sides of the critical section for punching shear}
\]

Eq. 2

\[
I_{33} = \sum_{sides = 1}^{n} I_{33}, \text{ where "sides" refers to the sides of the critical section for punching shear}
\]

Eq. 3

\[
I_{23} = \sum_{sides = 1}^{n} I_{23}, \text{ where "sides" refers to the sides of the critical section for punching shear}
\]

Eq. 4

The equations for \( I_{22}, I_{33}, \text{ and } I_{23} \) are different depending on whether the side of the critical section for punching shear being considered is parallel to the 2-axis or parallel to the 3-axis. Refer to Figures 9-4.
Figure 9-4 Shear Stress Calculations at Critical Sections

\[ T_{22} = Ld(y_2 - y_3)^2, \] for side of critical section parallel to 2-axis \hspace{1cm} \text{Eq. 5a}

\[ T_{22} = \frac{Ld^3}{12} + \frac{dL^3}{12} + Ld(y_2 - y_3)^2, \] for side of critical section parallel to 3-axis \hspace{1cm} \text{Eq. 5b}

\[ T_{33} = \frac{Ld^3}{12} + \frac{dL^3}{12} + Ld(x_2 - x_3)^2, \] for side of critical section parallel to 2-axis \hspace{1cm} \text{Eq. 6a}

\[ T_{33} = Ld(x_2 - x_3)^2, \] for side of critical section parallel to 3-axis \hspace{1cm} \text{Eq. 6b}
\[
\bar{T}_{23} = Ld (x_2 - x_3)(y_2 - y_3), \text{ for side of critical section parallel to 2-axis or 3-axis}
\]

Eq. 7

**NOTE:** \(\bar{T}_{23}\) is explicitly set to zero for corner condition.

where,

- \(b_0\) = Perimeter of the critical section for punching shear
- \(d\) = Effective depth at the critical section for punching shear based on the average of \(d\) for 2 direction and \(d\) for 3 direction
- \(I_{22}\) = Moment of inertia of the critical section for punching shear about an axis that is parallel to the local 2-axis
- \(I_{33}\) = Moment of inertia of the critical section for punching shear about an axis that is parallel to the local 3-axis
- \(I_{23}\) = Product of inertia of the critical section for punching shear with respect to the 2 and 3 planes
- \(L\) = Length of the side of the critical section for punching shear currently being considered
- \(M_{f2}\) = Moment about the line parallel to the 2-axis at the center of the column (positive in accordance with the right-hand rule)
- \(M_{f3}\) = Moment about the line parallel to the 3-axis at the center of the column (positive in accordance with the right-hand rule)
- \(V_f\) = Punching shear stress
- \(V_f\) = Shear at the center of the column (positive upward)
- \(x_1, y_1\) = Coordinates of the column centroid
- \(x_2, y_2\) = Coordinates of the center of one side of the critical section for punching shear
- \(x_3, y_3\) = Coordinates of the centroid of the critical section for punching shear
- \(x_4, y_4\) = Coordinates of the location where stress is being calculated
9.5.3.5 Determine Capacity Ratio

The ratio of the maximum shear stress and the concrete punching shear stress capacity is reported as the punching shear capacity ratio by ETABS. If this ratio exceeds 1.0, punching shear reinforcement is designed as described in the following section.

9.5.4 Design Punching Shear Reinforcement

The use of shear studs as shear reinforcement in slabs is permitted, provided that the effective depth of the slab is greater than or equal to 200 mm (CSA 13.2.1). If the slab thickness does not meet these requirements, the punching shear reinforcement is not designed, and the slab thickness should be increased by the user.

The algorithm for designing the required punching shear reinforcement is used when the punching shear capacity ratio exceeds unity. The Critical Section for Punching Shear and Transfer of Unbalanced Moment as described in the earlier sections remain unchanged. The design of punching shear reinforcement is performed as explained in the subsections that follow.

9.5.4.1 Determine Concrete Shear Capacity

The concrete punching shear stress capacity of a section with punching shear reinforcement is taken as:

\[ \nu_c = 0.28\lambda f_c \sqrt{f' c} \]  
for shear studs  \hspace{1cm} (CSA 13.3.8.3)

\[ \nu_c = 0.19\lambda f_c \sqrt{f' c} \]  
for shear stirrups  \hspace{1cm} (CSA 13.3.9.3)

9.5.4.2 Determine Required Shear Reinforcement

The shear force is limited to a maximum of \( \nu_{r,\text{max}} \), where

\[ \nu_{r,\text{max}} = 0.75\lambda f_c \sqrt{f' c} \]  
for shear studs  \hspace{1cm} (CSA 13.3.8.2)
\[ v_{r, \text{max}} = 0.55 \lambda \phi_c \sqrt{f'_c} \] for shear stirrups \hspace{1cm} \text{(CSA 13.3.9.2)}

Given \( v_f, v_c, \) and \( v_{r, \text{max}} \), the required shear reinforcement is calculated as follows, where, \( \phi_c \) is the strength reduction factor.

- If \( v_f > v_{r, \text{max}} \),
  \[ A_s = \frac{\left( v_f - v_c \right)}{\phi_c f'_{yy}} b_o \] \hspace{1cm} \text{(CSA 13.3.8.5, 13.3.9.4)}

- If \( v_f > v_{r, \text{max}} \), a failure condition is declared. \hspace{1cm} \text{(CSA 13.3.8.2)}

- If \( v_f \) exceeds the maximum permitted value of \( v_{r, \text{max}} \), the concrete section should be increased in size.

**9.5.4.3 Determine Reinforcement Arrangement**

Punching shear reinforcement in the vicinity of rectangular columns should be arranged on peripheral lines, i.e., lines running parallel to and at constant distances from the sides of the column. Figure 9-5 shows a typical arrangement of shear reinforcement in the vicinity of a rectangular interior, edge, and corner column.

![Figure 9-5 Typical arrangement of shear studs and critical sections outside shear-reinforced zone](image)
The distance between the column face and the first line of shear reinforcement shall not exceed

\[ 0.4d \text{ for shear studs} \quad (\text{CSA 13.3.8.6}) \]

\[ 0.25d \text{ for shear stirrups} \quad (\text{CSA 13.3.8.6}) \]

Punching shear reinforcement is most effective near column corners where there are concentrations of shear stress. Therefore, the minimum number of lines of shear reinforcement is 4, 6, and 8, for corner, edge, and interior columns respectively.

**9.5.4.4 Determine Reinforcement Diameter, Height, and Spacing**

The punching shear reinforcement is most effective when the anchorage is close to the top and bottom surfaces of the slab. The cover of anchors should not be less than the minimum cover specified in CSA 7.9 plus half of the diameter of the flexural reinforcement.

When specifying shear studs, the distance, \( s_o \), between the column face and the first peripheral line of shear studs should not be smaller than 0.4\(d\). The limits of \( s_o \) and the spacing, \( s \), between the peripheral lines are specified as:

\[
\begin{align*}
\text{If } v_f & \leq 0.56 \lambda \phi_c \sqrt{f'_c} \\
\quad & \text{then } s \leq 0.75d, \\
\text{If } v_f & > 0.56 \lambda \phi_c \sqrt{f'_c} \\
\quad & \text{then } s \leq 0.50d,
\end{align*}
\]

\( (\text{CSA 13.3.8.6}) \)

For shear stirrups,

\[
\begin{align*}
\text{If } v_f & \leq 0.56 \lambda \phi_c \sqrt{f'_c} \\
\quad & \text{then } s \leq 0.25d, \\
\text{If } v_f & > 0.56 \lambda \phi_c \sqrt{f'_c} \\
\quad & \text{then } s \leq 0.25d,
\end{align*}
\]

\( (\text{CSA 13.3.9.5}) \)

The minimum depth for reinforcement should be limited to 300 mm (CSA 13.3.9.1).
This chapter describes in detail the various aspects of the concrete design procedure that is used by ETABS when the European code Eurocode 2-2004 [EN 1992-1-1:2004] is selected. For the load combinations, reference is also made to Eurocode 0 [EN 1990], which is identified with the prefix “EC0.” Various notations used in this chapter are listed in Table 10-1. For referencing to the pertinent sections of the Eurocode in this chapter, a prefix “EC2” followed by the section number is used. It also should be noted that this section describes the implementation of the CEN Default version of Eurocode 2-2004, without a country specific National Annex. Where Nationally Determined Parameters [NDPs] are to be considered, this is highlighted in the respective section by the notation [NDP].

The design is based on user-specified loading combinations. However, the program provides a set of default load combinations that should satisfy requirements for the design of most building type structures.

English as well as SI and MKS metric units can be used for input. The code is based on Newton-millimeter-second units. For simplicity, all equations and descriptions presented in this chapter correspond to Newton-millimeter-second units unless otherwise noted.

10.2 Design Load Combinations

The design load combinations are the various combinations of the load cases for which the structure needs to be checked. Eurocode 0-2002 allows load combinations to be defined based on EC0 Equation 6.10 or the less favorable of EC0 Equations 6.10a and 6.10b \[NDP\].

\[
\sum_{j=1}^{\xi_j} \gamma_{G,j} G_{k,j} + \gamma_p P + \gamma_{Q,j,1} Q_{k,1} + \sum_{i=1}^{\gamma_{Q,j,i}} \psi_{0,i} Q_{k,i} \quad \text{(EC0 Eq. 6.10)}
\]

\[
\sum_{j=1}^{\xi_j} \gamma_{G,j} G_{k,j} + \gamma_p P + \gamma_{Q,j,1} \psi_{0,1} Q_{k,1} + \sum_{i=1}^{\gamma_{Q,j,i}} \gamma_{Q,j,i} \psi_{0,i} Q_{k,i} \quad \text{(EC0 Eq. 6.10a)}
\]

\[
\sum_{j=1}^{\xi_j} \gamma_{G,j} G_{k,j} + \gamma_p P + \gamma_{Q,j,1} Q_{k,1} + \sum_{i=1}^{\gamma_{Q,j,i}} \gamma_{Q,j,i} \psi_{0,i} Q_{k,i} \quad \text{(EC0 Eq. 6.10b)}
\]

Load combinations considering seismic loading are automatically generated based on EC0 Equation 6.12b.

\[
\sum_{j=1}^{\xi_j} G_{k,j} + P + A_{Ed} + \sum_{i=1}^{\gamma_{Q,j,i}} \psi_{2,i} Q_{k,i} \quad \text{(EC0 Eq. 6.12b)}
\]
For this code, if a structure is subjected to dead (D), live (L), pattern live (PL), snow (S), wind (W), and earthquake (E) loads, and considering that wind and earthquake forces are reversible, the following load combinations need to be considered if equation 6.10 is specified for generation of the load combinations (EC0 6.4.3):

\[
\begin{align*}
\gamma_{Gj,\text{sup}} D & \quad \text{(EC0 Eq. 6.10)} \\
\gamma_{Gj,\text{sup}} D + \gamma_{Q,1} L & \quad \text{(EC0 Eq. 6.10)} \\
\gamma_{Gj,\text{sup}} D + (0.75)\gamma_{Q,1} PL & \quad \text{(EC0 Eq. 6.10)} \\
\gamma_{Gj,\text{inf}} D \pm \gamma_{Q,1} W & \quad \text{(EC0 Eq. 6.10)} \\
\gamma_{Gj,\text{sup}} D \pm \gamma_{Q,1} W & \quad \text{(EC0 Eq. 6.10)} \\
\gamma_{Gj,\text{sup}} D + \gamma_{Q,1} L \pm \gamma_{Q,i} \psi_{0,i} W & \quad \text{(EC0 Eq. 6.10)} \\
\gamma_{Gj,\text{sup}} D + \gamma_{Q,1} L + \gamma_{Q,i} \psi_{0,i} S & \quad \text{(EC0 Eq. 6.10)} \\
\gamma_{Gj,\text{sup}} D \pm \gamma_{Q,1} W + \gamma_{Q,i} \psi_{0,i} L & \quad \text{(EC0 Eq. 6.10)} \\
\gamma_{Gj,\text{sup}} D \pm \gamma_{Q,1} W + \gamma_{Q,i} \psi_{0,i} S & \quad \text{(EC0 Eq. 6.10)} \\
\gamma_{Gj,\text{sup}} D + \gamma_{Q,1} S \pm \gamma_{Q,i} \psi_{0,i} W & \quad \text{(EC0 Eq. 6.10)} \\
\gamma_{Gj,\text{sup}} D + \gamma_{Q,1} S + \gamma_{Q,i} \psi_{0,i} L & \quad \text{(EC0 Eq. 6.10)} \\
\gamma_{Gj,\text{sup}} D + \gamma_{Q,1} L + \gamma_{Q,i} \psi_{0,i} S \pm \gamma_{Q,i} \psi_{0,i} W & \quad \text{(EC0 Eq. 6.10)} \\
\gamma_{Gj,\text{sup}} D \pm \gamma_{Q,1} W + \gamma_{Q,i} \psi_{0,i} S + \gamma_{Q,i} \psi_{0,i} L & \quad \text{(EC0 Eq. 6.10)} \\
D \pm 1.0E & \quad \text{(EC0 Eq. 6.12b)} \\
D \pm 1.0E + \psi_{2,i} L & \quad \text{(EC0 Eq. 6.12b)} \\
D \pm 1.0E + \psi_{2,i} L + \psi_{2,i} S & \quad \text{(EC0 Eq. 6.12b)}
\end{align*}
\]

If the load combinations are specified to be generated from the max of EC0 Equations 6.10a and 6.10b, the following load combinations from both equations are considered in the program.

\[
\begin{align*}
\gamma_{Gj,\text{sup}} D & \quad \text{(EC0 Eq. 6.10a)} \\
\xi \gamma_{Gj,\text{sup}} D & \quad \text{(EC0 Eq. 6.10b)} \\
\gamma_{Gj,\text{sup}} D + \gamma_{Q,1} \psi_{0,i} L & \quad \text{(EC0 Eq. 6.10a)} \\
\xi \gamma_{Gj,\text{sup}} D + \gamma_{Q,1} L & \quad \text{(EC0 Eq. 6.10b)}
\end{align*}
\]
\[
\begin{align*}
\gamma_{Gj,\text{sup}} D &+ (0.75) \gamma_{Q,1} \psi_{0,1} PL & \text{(EC0 Eq. 6.10a)} \\
\zeta \gamma_{Gj,\text{sup}} D &+ (0.75) \gamma_{Q,1} PL & \text{(EC0 Eq. 6.10b)} \\
\gamma_{Gj,\text{inf}} D &\pm \gamma_{Q,1} \psi_{0,1} W & \text{(EC0 Eq. 6.10a)} \\
\gamma_{Gj,\text{sup}} D &\pm \gamma_{Q,1} \psi_{0,1} W & \text{(EC0 Eq. 6.10b)} \\
\gamma_{Gj,\text{inf}} D &\pm \gamma_{Q,1} W & \text{(EC0 Eq. 6.10b)} \\
\zeta \gamma_{Gj,\text{sup}} D &\pm \gamma_{Q,1} W & \text{(EC0 Eq. 6.10b)} \\
\gamma_{Gj,\text{sup}} D &+ \gamma_{Q,1} \psi_{0,1} L \pm \gamma_{Q,i} \psi_{0,i} W & \text{(EC0 Eq. 6.10a)} \\
\gamma_{Gj,\text{sup}} D &+ \gamma_{Q,1} \psi_{0,1} L + \gamma_{Q,i} \psi_{0,i} S & \text{(EC0 Eq. 6.10b)} \\
\gamma_{Gj,\text{sup}} D &+ \gamma_{Q,1} \psi_{0,1} W + \gamma_{Q,i} \psi_{0,i} L & \text{(EC0 Eq. 6.10a)} \\
\gamma_{Gj,\text{sup}} D &+ \gamma_{Q,1} \psi_{0,1} S + \gamma_{Q,i} \psi_{0,i} L & \text{(EC0 Eq. 6.10b)} \\
\gamma_{Gj,\text{inf}} D &+ \gamma_{Q,1} \psi_{0,1} S \pm \gamma_{Q,i} \psi_{0,i} W & \text{(EC0 Eq. 6.10a)} \\
\gamma_{Gj,\text{inf}} D &+ \gamma_{Q,1} \psi_{0,1} S + \gamma_{Q,i} \psi_{0,i} L & \text{(EC0 Eq. 6.10b)} \\
\zeta \gamma_{Gj,\text{sup}} D &+ \gamma_{Q,1} L \pm \gamma_{Q,i} \psi_{0,i} W & \text{(EC0 Eq. 6.10a)} \\
\zeta \gamma_{Gj,\text{sup}} D &+ \gamma_{Q,1} L + \gamma_{Q,i} \psi_{0,i} S & \text{(EC0 Eq. 6.10b)} \\
\zeta \gamma_{Gj,\text{sup}} D &+ \gamma_{Q,1} S \pm \gamma_{Q,i} \psi_{0,i} W & \text{(EC0 Eq. 6.10a)} \\
\zeta \gamma_{Gj,\text{sup}} D &+ \gamma_{Q,1} S + \gamma_{Q,i} \psi_{0,i} L & \text{(EC0 Eq. 6.10b)} \\
\gamma_{Gj,\text{inf}} D &\pm \gamma_{Q,1} W + \gamma_{Q,i} \psi_{0,i} L & \text{(EC0 Eq. 6.10a)} \\
\gamma_{Gj,\text{inf}} D &\pm \gamma_{Q,1} W + \gamma_{Q,i} \psi_{0,i} S & \text{(EC0 Eq. 6.10b)} \\
D &\pm 1.0E & \text{(EC0 Eq. 6.12b)} \\
D &\pm 1.0E + \psi_{2,i} L & \text{(EC0 Eq. 6.12b)} \\
D &\pm 1.0E + \psi_{2,i} L + \psi_{2,i} S & \text{(EC0 Eq. 6.12b)}
\end{align*}
\]

For both sets of load combinations, the variable values for the CEN Default version of the load combinations are defined in the list that follows [NDP].

\[
\begin{align*}
\gamma_{Gj,\text{sup}} &= 1.35 & \text{(EC0 Table A1.2(B))} \\
\gamma_{Gj,\text{inf}} &= 1.00 & \text{(EC0 Table A1.2(B))} \\
\gamma_{Q,1} &= 1.5 & \text{(EC0 Table A1.2(B))} \\
\gamma_{Q,i} &= 1.5 & \text{(EC0 Table A1.2(B))} \\
\psi_{0,i} &= 0.7 \text{ (live load, assumed not to be storage)} & \text{(EC0 Table A1.1)} \\
\psi_{0,i} &= 0.6 \text{ (wind load)} & \text{(EC0 Table A1.1)} \\
\psi_{0,i} &= 0.5 \text{ (snow load, assumed } H \leq 1,000 \text{ m)} & \text{(EC0 Table A1.1)}
\end{align*}
\]
Chapter 10 - Design for Eurocode 2-2004

\[ \xi = 0.85 \]  
(\text{EC0 Table A1.2(B)})

\[ \psi_{2,i} = 0.3 \]  
(live, assumed office/residential space)  
(\text{EC0 Table A1.1})

\[ \psi_{2,i} = 0 \]  
(snow, assumed \( H \leq 1,000 \) m)  
(\text{EC0 Table A1.1})

These are also the default design load combinations in ETABS whenever the Eurocode 2-2004 code is used. If roof live load is treated separately or other types of loads are present, other appropriate load combinations should be used.

10.3 Limits on Material Strength

The concrete compressive strength, \( f_{ck} \), should not be greater than 90 MPa (EC2 3.1.2(2)). The lower and upper limits of the reinforcement yield strength, \( f_{yk} \), should be 400 and 600 MPa, respectively (EC2 3.2.2(3)).

ETABS enforces the upper material strength limits for flexure and shear design of slabs. The input material strengths are taken as the upper limits if they are defined in the material properties as being greater than the limits. It is the user's responsibility to ensure that the minimum strength is satisfied.

10.4 Partial Safety Factors

The design strengths for concrete and steel are obtained by dividing the characteristic strengths of the materials by the partial safety factors, \( \gamma_s \) and \( \gamma_c \), as shown here [\text{NDP}].

\[
 f_{cd} = \alpha_{cc} f_{ck} / \gamma_c \]  
(EC2 3.1.6(1))

\[
 f_{yd} = f_{yk} / \gamma_s \]  
(EC2 3.2.7(2))

\[
 f_{yd} = f_{yk} / \gamma_s \]  
(EC2 3.2.7(2))

\( \alpha_{cc} \) is the coefficient taking account of long term effects on the compressive strength. \( \alpha_{cc} \) is taken as 1.0 by default and can be overwritten by the user (EC2 3.1.6(1)).
The partial safety factors for the materials and the design strengths of concrete and reinforcement are given in the text that follows (EC2 2.4.2.4(1), Table 2.1N):

Partial safety factor for reinforcement, $\gamma_s = 1.15$

Partial safety factor for concrete, $\gamma_c = 1.5$

These values are recommended by the code to give an acceptable level of safety for normal structures under regular design situations (EC2 2.4.2.4). For accidental and earthquake situations, the recommended values are less than the tabulated values. The user should consider those separately.

These values can be overwritten; however, caution is advised.

### 10.5 Slab Design

ETABS slab design procedure involves defining sets of strips in two mutually perpendicular directions. The locations of the strips are usually governed by the locations of the slab supports. The axial force, moments and shears for a particular strip are recovered from the analysis (on the basis of the Wood-Armer technique), and a flexural design is carried out based on the ultimate strength design method.

The slab design procedure involves the following steps:

- Design flexural reinforcement
- Design shear reinforcement
- Punching check

#### 10.5.1 Design Flexural Reinforcement

For slabs, ETABS uses either design strips or the finite element based design to calculate the slab flexural reinforcement in accordance with the selected design code. For simplicity, only strip-by-strip design is documented in the proceeding sections.

The design of the slab reinforcement for a particular strip is carried out at specific locations along the length of the strip. These locations correspond to the element
boundaries. Controlling reinforcement is computed on either side of those element boundaries. The slab flexural design procedure for each load combination involves the following:

- Determine factored axial loads and moments for each slab strip.
- Design flexural reinforcement for the strip.
- These two steps, described in the text that follows, are repeated for every load combination. The maximum reinforcement calculated for the top and bottom of the slab within each design strip, along with the corresponding controlling load combination, is obtained and reported.

10.5.1.1 Determine Factored Moments

In the design of flexural reinforcement of concrete slab, the factored moments for each load combination at a particular design strip are obtained by factoring the corresponding moments for different load cases, with the corresponding load factors.

The slab is then designed for the maximum positive and maximum negative factored moments obtained from all of the load combinations. Calculation of bottom reinforcement is based on positive design strip moments. In such cases, the slab may be designed as a rectangular or flanged slab section. Calculation of top reinforcement is based on negative design strip moments. In such cases, the slab may be designed as a rectangular or inverted flanged slab section.

10.5.1.2 Determine Required Flexural Reinforcement

In the flexural reinforcement design process, the program calculates both the tension and compression reinforcement. Compression reinforcement is added when the applied design moment exceeds the maximum moment capacity of a singly reinforced section. The user has the option of avoiding compression reinforcement by increasing the effective depth, the width, or the strength of the concrete.

The design procedure is based on the simplified rectangular stress block shown in Figure 10-1 (EC2 3.1.7(3)). The area of the stress block and the depth of the compressive block is taken as:
\[ F_c = \eta f_{cd} ab \]  
\[ a = \lambda x \]

where \( x \) is the depth of the neutral axis. The factor \( \lambda \) defining the effective height of the compression zone and the factor \( \eta \) defining the effective strength are given as:

\[ \lambda = 0.8 \quad \text{for} \quad f_{ck} \leq 50 \text{ MPa} \]  
\[ \lambda = 0.8 \left( \frac{f_{ck} - 50}{400} \right) \quad \text{for} \quad 50 < f_{ck} \leq 90 \text{ MPa} \]  
\[ \eta = 1.0 \quad \text{for} \quad f_{ck} \leq 50 \text{ MPa} \]  
\[ \eta = 1.0 - \left( \frac{f_{ck} - 50}{200} \right) \quad \text{for} \quad 50 < f_{ck} \leq 90 \text{ MPa} \]

Furthermore, it is assumed that moment redistribution in the member does not exceed the code-specified limiting value. The code also places a limitation on the neutral axis depth, to safeguard against non-ductile failures (EC2 5.5(4)). When the applied moment exceeds the limiting moment capacity as a singly reinforced slab, the area of compression reinforcement is calculated assuming that the neutral axis depth remains at the maximum permitted value.

The limiting value of the ratio of the neutral axis depth at the ultimate limit state to the effective depth, \( \left( \frac{x}{d} \right)_{\text{lim}} \), is expressed as a function of the ratio of the redistributed moment to the moment before redistribution, \( \delta \), as follows:

\[ \left( \frac{x}{d} \right)_{\text{lim}} = \frac{\delta - k_1}{k_2} \quad \text{for} \quad f_{ck} \leq 50 \text{ MPa} \]  
\[ \left( \frac{x}{d} \right)_{\text{lim}} = \frac{\delta - k_3}{k_4} \quad \text{for} \quad f_{ck} > 50 \text{ MPa} \]  

For reinforcement with \( f_{yk} \leq 500 \text{ MPa} \), the following values are used:

\[ k_i = 0.44 \left[ NDP \right] \]  

10 - 10 Slab Design
Chapter 10 - Design for Eurocode 2-2004

\[ k_2 = k_4 = 1.25(0.6 + 0.0014/\varepsilon_{cu2}) \] [NDP] \hspace{1cm} (EC 5.5(4))

\[ k_3 = 0.54 \] [NDP] \hspace{1cm} (EC 5.5(4))

\( \delta \) is assumed to be 1

where the ultimate strain, \( \varepsilon_{cu2} \) [NDP], is determined from EC2 Table 3.1 as:

\[ \varepsilon_{cu2} = 0.0035 \text{ for } f_{ck} < 50 \text{ MPa} \] (EC2 Table 3.1)

\[ \varepsilon_{cu2} = 2.6 + 35\left(\frac{90 - f_{ck}}{100}\right)^4 \text{ for } f_{ck} \geq 50 \text{ MPa} \] (EC2 Table 3.1)

The design procedure used by ETABS, for both rectangular and flanged sections (L- and T-shaped sections), is summarized in the subsections that follow.

---

**Figure 10-1 Uniform Thickness Slab Design**
10.5.1.2.1 Design of uniform thickness slab

For uniform thinness slab, the normalized moment, \( m \), and the normalized section capacity as a singly reinforce slab, \( m_{\text{lim}} \), are obtained first. The reinforcement area is determined based on whether \( m \) is greater than, less than, or equal to \( m_{\text{lim}} \).

- The normalized design moment, \( m \), is calculated as:

\[
m = \frac{M}{bd^2\eta_{cd}}
\]

- The normalized concrete moment capacity as a singly reinforced slab, \( m_{\text{lim}} \), is calculated as:

\[
m_{\text{lim}} = \lambda \left( \frac{x}{d} \right)_{\lim} \left[ 1 - \frac{\lambda}{2} \left( \frac{x}{d} \right)_{\lim} \right]
\]

- If \( m \leq m_{\text{lim}} \), a singly reinforced slab is designed. The normalized reinforcement ratio is calculated as:

\[
\omega = 1 - \sqrt{1 - 2m}
\]

The area of tension reinforcement, \( A_s \), is then given by:

\[
A_s = \omega \left( \frac{\eta_{cd} bd}{f_{cd}} \right)
\]

This reinforcement is to be placed at the bottom if \( M_{Ed} \) is positive, or at the top if \( M_{Ed} \) is negative.

- If \( m > m_{\text{lim}} \), both tension and compression reinforcement is designed as follows:

The normalized steel ratios \( \omega', \omega_{\text{lim}} \), and \( \omega \) are calculated as:

\[
\omega_{\text{lim}} = \lambda \left( \frac{x}{d} \right)_{\lim} = 1 - \sqrt{1 - 2m_{\text{lim}}}
\]

\[
\omega' = \frac{m - m_{\text{lim}}}{1 - d'/d}
\]
\[ \omega = \omega_{lim} + \omega' \]

where, \( d' \) is the depth to the compression reinforcement from the concrete compression face.

The area of compression and tension reinforcement, \( A'_s \) and \( A_s \), are given by:

\[
A'_s = \omega' \left[ \frac{\eta f_{cd} bd}{f'_s - \eta f_{cd}} \right]
\]

\[
A_s = \omega \left[ \frac{\eta f'_c bd}{f_{yd}} \right]
\]

where, \( f'_s \) is the stress in the compression reinforcement, and is given by:

\[
f'_s = E_s \varepsilon_{cu3} \left[ 1 - \frac{d'}{x_{lim}} \right] \leq f_{yd} \]  

(EC2 6.1, 3.2.7(4), Fig 3.8)

10.5.1.2.2 Design of nonuniform thickness slab

10.5.1.2.2.1 Flanged Slab Section Under Negative Moment

In designing for a factored negative moment, \( M_{Ed} \) (i.e., designing top reinforcement), the calculation of the reinforcement area is exactly the same as described previously, i.e., no flanged data is used.

10.5.1.2.2.2 Flanged Slab Section Under Positive Moment

With the flange in compression, the program analyzes the section by considering alternative locations of the neutral axis. Initially, the neutral axis is assumed to be located within the flange. Based on this assumption, the program calculates the depth of the neutral axis. If the stress block does not extend beyond the flange thickness, the section is designed as a uniform thickness slab of width \( b_f \). If the stress block extends beyond the flange, additional calculation is required. See Figure 10-2.

- The normalized design moment, \( m \), is calculated as:
ETABS Reinforced Concrete Design

\[ m = \frac{M}{bd^2\eta f_{cd}} \]  

(EC2 6.1, 3.1.7(3))

- The limiting values are calculated as:

\[ m_{\text{lim}} = \lambda \left( \frac{x}{d} \right)_{\text{lim}} \left[ 1 - \frac{\lambda}{2} \left( \frac{x}{d} \right)_{\text{lim}} \right] \]  

(EC2 5.5(4), 3.1.7(3))

\[ \omega_{\text{lim}} = \lambda \left( \frac{x}{d} \right)_{\text{lim}} \]

\[ a_{\text{max}} = \omega_{\text{lim}} d \]

- The values \( \omega \) and \( a \) are calculated as:

\[ \omega = 1 - \sqrt{1 - 2m} \]

\[ a = \omega d \]

**Figure 10-2 Nonuniform Thickness Slab Design**

- If \( a \leq h_f \), the subsequent calculations for \( A_s \) are exactly the same as previously defined for the uniform thickness slab design. However, in that case, the width of the slab is taken as \( b_f \). Compression reinforcement is required when \( m > m_{\text{lim}} \).
If $a > h_f$, the calculation for $A_s$ has two parts. The first part is for balancing the compressive force from the flange, and the second part is for balancing the compressive force from the web, as shown in Figure 10-2. The reinforcement area required for balancing the flange compression, $A_{s2}$ is given as:

$$
A_{s2} = \frac{(b_f - b_w) h_f \eta f_{cd}}{f_{yd}}
$$

and the corresponding resistive moment is given by

$$
M_2 = A_{s2} f_{yd} \left( d - \frac{h_f}{2} \right)
$$

The reinforcement required for balancing the compressive force from the web, considering a rectangular section of width $b_w$ to resist the moment, $M_1 = M - M_2$, is determined as follows:

$$
m_1 = \frac{M_1}{b_w d^2 \eta f_{cd}}
$$

- If $m_1 \leq m_{\text{lim}}$,

  $$
  \omega_1 = 1 - \sqrt{1 - 2m_1}
  $$

  $$
  A_{s1} = \omega_1 \left[ \frac{\eta f_{cd} b_w d}{f_{yd}} \right]
  $$

- If $m_1 > m_{\text{lim}}$,

  $$
  \omega' = \frac{m_1 - m_{\text{lim}}}{1 - d'/d}
  $$

  $$
  \omega_{\text{lim}} = \lambda \left( \frac{x}{d} \right)_{\text{lim}}
  $$

  $$
  \omega_1 = \omega_{\text{lim}} + \omega'
  $$
\[ A'_t = \omega \left[ \frac{\eta f'_{cd} b d}{f'_t - \eta f_{cd}} \right] \]

\[ A_{s1} = \omega_1 \left[ \frac{\eta f'_{cd} b_u d}{f_{yd}} \right] \]

where, \( f'_t \) is given by:

\[ f'_t = E_s \varepsilon_{ck,3} \left[ 1 - \frac{d'}{x_{lim}} \right] \leq f_{yd} \quad \text{(EC2 6.1, 3.2.7(4), Fig 3.8)} \]

The total tension reinforcement is \( A_t = A_{s1} + A_{s2} \), and the total compression reinforcement is \( A'_t \). \( A_s \) is to be placed at the bottom and \( A'_t \) is to be placed at the top.

10.5.1.3 Minimum and Maximum Reinforcement

The minimum flexural tension reinforcement required for each direction of a slab is given by the following limits (EC2 9.3.1.1) [NDP]:

\[ A_{s,\text{min}} = 0.26 \frac{f'_{cm}}{f'_{yk}} \quad \text{(EC2 9.2.1.1(1))} \]

\[ A_{s,\text{min}} = 0.0013 b d \quad \text{(EC2 9.2.1.1(1))} \]

where \( f'_{cm} \) is the mean value of axial tensile strength of the concrete and is computed as:

\[ f'_{cm} = 0.30 f'_{ck} \quad \text{for} \quad f_{ck} \leq 50 \text{ MPa} \quad \text{(EC2 Table 3.1)} \]

\[ f'_{cm} = 2.12 \ln \left( 1 + f'_{cm}/10 \right) \quad \text{for} \quad f_{ck} > 50 \text{ MPa} \quad \text{(EC2 Table 3.1)} \]

\[ f'_{cm} = f_{ck} + 8 \text{ MPa} \quad \text{(EC2 Table 3.1)} \]

The minimum flexural tension reinforcement required for control of cracking should be investigated independently by the user.

An upper limit on the tension reinforcement and compression reinforcement has been imposed to be 0.04 times the gross cross-sectional area (EC 9.2.1.1(3)).
10.5.2 Design Slab Shear Reinforcement

The shear reinforcement is designed for each load combination at each station along the design strip. In designing the shear reinforcement for a particular strip, for a particular load combination, at a particular station due to the slab major shear, the following steps are involved (EC2 6.2):

- Determine the factored shear force, \( V_{Ed} \).
- Determine the shear force, \( V_{Rd,c} \), that can be resisted by the concrete.
- Determine the shear reinforcement required.

The following three sections describe in detail the algorithms associated with these steps.

10.5.2.1 Determine Factored Shear Force

In the design of the slab shear reinforcement, the shear forces for each load combination at a particular design strip station are obtained by factoring the corresponding shear forces for different load cases, with the corresponding load combination factors.

10.5.2.2 Determine Concrete Shear Capacity

The shear force carried by the concrete, \( V_{Rd,c} \), is calculated as:

\[
V_{Rd,c} = \left[ C_{Rd,c} k \left( 100 \rho f_{ck} \right)^{1/3} + k_1 \sigma_{sp} \right] b_n d
\]

(\( \text{EC2 } 6.2.2(1) \))

with a minimum of:

\[
V_{Rd,c} = \left( v_{\text{min}} + k_1 \sigma_{sp} \right) b_n d
\]

(\( \text{EC2 } 6.2.2(1) \))

where

- \( f_{ck} \) is in MPa

\[
k = 1 + \sqrt{\frac{200}{d}} \leq 2.0 \text{ with } d \text{ in mm}
\]

(\( \text{EC2 } 6.2.2(1) \))
The value of $C_{Rd,c}$, $\nu_{\text{min}}$, and $k_1$, for use in a country may be found in its National Annex. The program default values for $C_{Rd,c}$ [NDP], $\nu_{\text{min}}$ [NDP], and $k_1$ [NDP] are given as follows (EC2 6.2.2(1)):

$$C_{Rd,c} = 0.18/\gamma_c$$  

(EC2 6.2.2(1))

$$\nu_{\text{min}} = 0.035 \, k^{3/2} \, f_{ck}^{1/2}$$  

(EC2 6.2.2(1))

$$k_1 = 0.15.$$  

(EC2 6.2.2(1))

For lightweight concrete:

$$C_{Rd,c} = 0.18/\gamma_c$$  

(EC2 11.6.1(1))

$$\nu_{\text{min}} = 0.03 \, k^{3/2} \, f_{ck}^{1/2}$$  

(EC2 11.6.1(1))

$$k_1 = 0.15.$$  

(EC2 11.6.1(1))

### 10.5.2.3 Determine Required Shear Reinforcement

The shear force is limited to a maximum of:

$$V_{Rd,\text{max}} = \frac{\alpha_{cw} b_w z \nu_1 f_{cd}}{\cot \theta + \tan \theta}, \text{ where}$$  

EC2 6.2.3(3)

$\alpha_{cw}$ [NDP] is conservatively taken as 1.  

EC2 6.2.3(3)

The strength reduction factor for concrete cracked in shear, $\nu_1$ [NDP], is defined as:

$$\nu_1 = 0.6 \left(1 - \frac{f_{ck}}{250}\right)$$  

EC2 6.2.2(6)

$$z = 0.9d$$  

EC2 6.2.3(1)
\( \theta \) is optimized by the program and is set to 45\(^\circ\) for combinations including seismic loading (EC2 6.2.3(2)).

Given \( V_{Ed}, V_{Rdc}, \) and \( V_{Rd,max} \), the required shear reinforcement is calculated as follows:

- If \( V_{Ed} \leq V_{Rdc} \),
  \[
  \frac{A_{sw}}{s_y} = \frac{A_{sw,\text{min}}}{s}
  \]

- If \( V_{R,dc} < V_{Ed} \leq V_{Rd,max} \)
  \[
  \frac{A_{sw}}{s} = \frac{V_{Ed}}{z f_{yw} \cot \theta} \geq \frac{A_{sw,\text{min}}}{s}
  \]  \hspace{1cm} (EC2 6.2.3(3))

- If \( V_{Ed} > V_{Rd,max} \), a failure condition is declared. \hspace{1cm} (EC2 6.2.3(3))

The minimum shear reinforcement is defined as:

\[
\frac{A_{sw,\text{min}}}{s} = \frac{0.08 \sqrt{f_{ck}} b_w}{f_{yk}}
\]  \hspace{1cm} (EC2 9.2.2(5))

The maximum of all of the calculated \( A_{sw}/s_y \) values obtained from each load combination is reported along with the controlling shear force and associated load combination.

The slab shear reinforcement requirements considered by the program are based purely on shear strength considerations. Any minimum stirrup requirements to satisfy spacing and volumetric considerations must be investigated independently of the program by the user.

### 10.5.3 Check for Punching Shear

The algorithm for checking punching shear is detailed in the section entitled “Slab Punching Shear Check” in the *Key Features and Terminology* manual. Only the code-specific items are described in the following subsections.
10.5.3.1 Critical Section for Punching Shear

The punching shear is checked at the face of the column (EC2 6.4.1(4)) and at a critical section at a distance of $2.0d$ from the face of the support (EC2 6.4.2(1)). The perimeter of the critical section should be constructed such that its length is minimized. Figure 10-3 shows the auto punching perimeters considered by ETABS for the various column shapes. The column location (i.e., interior, edge, corner) and the punching perimeter may be overwritten using the Punching Check Overwrites.

![Figure 10-3 Punching Shear Perimeters](image)

10.5.3.2 Determination of Concrete Capacity

The concrete punching shear stress capacity is taken as:

$$
V_{Rd,c} = C_{Rd,c} k \left( 100 \rho c f_{ck} \right)^{1/3} + k_1 \sigma_{cp} 
$$

(EC2 6.4.4(1))

with a minimum of:

$$
V_{Rd,c} = \left( V_{\min} + k_1 \sigma_{cp} \right) 
$$

(EC2 6.4.4(1))

where $f_{ck}$ is in MPa and
$k = 1 + \sqrt{\frac{200}{d}} \leq 2.0$ with $d$ in mm \hspace{1cm} (EC2 6.4.4(1))

$\rho_t = \sqrt{\rho_{1x}\rho_{1y}} \leq 0.02$ \hspace{1cm} (EC2 6.4.4(1))

where $\rho_{1x}$ and $\rho_{1y}$ are the reinforcement ratios in the $x$ and $y$ directions respectively, which is taken as the average tension reinforcement ratios of design strips in Layer A and layer B where Layer A and Layer design strips are in orthogonal directions. When design strips are not present in both orthogonal directions then tension reinforcement ratio is taken as zero in the current implementation, and

$\sigma_{cp} = \left(\sigma_{cx} + \sigma_{cy}\right)/2$ \hspace{1cm} (EC2 6.4.4(1))

where $\sigma_{cx}$ and $\sigma_{cy}$ are the normal concrete stresses in the critical section in the $x$ and $y$ directions respectively, conservatively taken as zeros.

$C_{rd,c} = 0.18/\gamma_c \text{ [NDP]}$ \hspace{1cm} (EC2 6.4.4(1))

$v_{\min} = 0.035k^{3/2}f_{ck}^{1/2} \text{ [NDP]}$ \hspace{1cm} (EC2 6.4.4(1))

$k_t = 0.15 \text{ [NDP]}$. \hspace{1cm} (EC2 6.4.4(1))

**10.5.3.3 Determine Maximum Shear Stress**

Given the punching shear force and the fractions of moments transferred by eccentricity of shear, the nominal design shear stress, $v_{Ed}$, is calculated as:

$v_{Ed} = \frac{V_{Ed}}{ud} \left[1 + k \frac{M_{Ed,2}u_1}{V_{Ed}W_{1,2}} + k \frac{M_{Ed,3}u_1}{V_{Ed}W_{1,3}}\right]$, where \hspace{1cm} (EC2 6.4.4(2))

$k$ is the function of the aspect ratio of the loaded area in Table 6.1 of EN 1992-1-1

$u_1$ is the effective perimeter of the critical section

$d$ is the mean effective depth of the slab

$M_{Ed}$ is the design moment transmitted from the slab to the column at the connection along bending axis 2 and 3.
$V_{Ed}$ is the total punching shear force

$W_i$ accounts for the distribution of shear based on the control perimeter along bending axis 2 and 3.

### 10.5.3.4 Determine Capacity Ratio

The ratio of the maximum shear stress and the concrete punching shear stress capacity is reported as the punching shear capacity ratio by ETABS. If this ratio exceeds 1.0, punching shear reinforcement is designed as described in the following section.

### 10.5.4 Design Punching Shear Reinforcement

The use of shear studs as shear reinforcement in slabs is permitted, provided that the effective depth of the slab is greater than or equal to 200 mm.

The algorithm for designing the required punching shear reinforcement is used when the punching shear capacity ratio exceeds unity. The Critical Section for Punching Shear and Transfer of Unbalanced Moment as described in the earlier sections remain unchanged. The design of punching shear reinforcement is performed as described in the subsections that follow.

### 10.5.4.1 Determine Concrete Shear Capacity

The concrete punching shear stress capacity of a section with punching shear reinforcement is as previously determined for the punching check.

### 10.5.4.2 Determine Required Shear Reinforcement

The shear is limited to a maximum of $V_{Rd,max}$ calculated in the same manner as explained previously for slabs.

Given $V_{Ed}$, $V_{Rd,c}$, and $V_{Rd,max}$, the required shear reinforcement is calculated as follows (EC2 6.4.5).

- If $V_{Rd,c} < V_{Ed} \leq V_{Rd,max}$
\[
A_{sw} = \frac{\left( v_{Ed} - 0.75v_{Rd,max} \right)}{1.5f_{ywd,ef}} (u_i d) s_r
\]  
(EC2 6.4.5)

- If \( v_{Ed} > v_{Rd,max} \), a failure condition is declared. (EC2 6.2.3(3))
- If \( v_{Ed} \) exceeds the maximum permitted value of \( V_{Rd,max} \), the concrete section should be increased in size.

### 10.5.4.3 Determine Reinforcement Arrangement

Punching shear reinforcement in the vicinity of rectangular columns should be arranged on peripheral lines, i.e., lines running parallel to and at constant distances from the sides of the column. Figure 10-4 shows a typical arrangement of shear reinforcement in the vicinity of a rectangular interior, edge, and corner column.

The distance between the column face and the first line of shear reinforcement shall not exceed \( 2d \). The spacing between adjacent shear reinforcement in the first line (perimeter) of shear reinforcement shall not exceed \( 1.5d \) measured in a direction parallel to the column face (EC2 9.4.3(1)).

Punching shear reinforcement is most effective near column corners where there are concentrations of shear stress. Therefore, the minimum number of lines of
shear reinforcement is 4, 6, and 8, for corner, edge, and interior columns respectively.

### 10.5.4.4 Determine Reinforcement Diameter, Height, and Spacing

The punching shear reinforcement is most effective when the anchorage is close to the top and bottom surfaces of the slab. The cover of anchors should not be less than the minimum cover specified in EC2 4.4.1 plus half of the diameter of the flexural reinforcement.

Punching shear reinforcement in the form of shear studs is generally available in 10-, 12-, 14-, 110-, and 20-millimeter diameters.

When specifying shear studs, the distance, $s_o$, between the column face and the first peripheral line of shear studs should not be smaller than $0.3d$. The spacing between adjacent shear studs, $g$, at the first peripheral line of studs shall not exceed $1.5d$ and should not exceed $2d$ at additional perimeters. The limits of $s_o$ and the spacing, $s$, between the peripheral lines are specified as:

\[
0.3d \leq s_o \leq 2d \quad \text{(EC2 9.4.3(1))}
\]

\[
s \leq 0.75d \quad \text{(EC2 9.4.3(1))}
\]

\[
g \leq 1.5d \text{ (first perimeter)} \quad \text{(EC2 9.4.3(1))}
\]

\[
g \leq 2d \text{ (additional perimeters)} \quad \text{(EC2 9.4.3(1))}
\]

### 10.6 Nationally Determined Parameters (NDPs)

The Comité Européen de Normalisation (CEN) version of Eurocode 2-2004 specifies a set of clauses in the design code, for which Nationally Determined Parameters [NDPs] are permitted to be adjusted by each member country within their National Annex. Variations in these parameters between countries are considered in the program by choosing the desired country from the Options menu > Preferences > Concrete Frame Design command. This appendix lists the NDPs as adopted in the program for the CEN Default version of the design code. Additional tables are provided that list the NDPs that differ from the CEN Default values for each country supported in the program.

Chapter 11
Design for Hong Kong CP-2013

This chapter describes in detail the various aspects of the concrete design procedure that is used by ETABS when the Hong Kong limit state code CP-2013 [CP 2013] is selected. The various notations used in this chapter are listed in Table 11-1. For referencing to the pertinent sections of the Hong Kong code in this chapter, a prefix “CP” followed by the section number is used.

The design is based on user-specified load combinations. The program provides a set of default load combinations that should satisfy the requirements for the design of most building type structures.

English as well as SI and MKS metric units can be used for input. The code is based on Newton-millimeter-second units. For simplicity, all equations and descriptions presented in this chapter correspond to Newton-millimeter-second units unless otherwise noted.

### 11.2 Design Load Combinations

The design load combinations are the various combinations of the load cases for which the structure needs to be designed. The design load combinations are obtained by multiplying the characteristic loads by appropriate partial factors of safety, $\gamma_f$ (CP 2.3.1.3). For CP-2013, if a structure is subjected to dead (G), live
(Q), pattern live (PQ), and wind (W) loads, and considering that wind forces are reversible, the following load combinations may need to be considered. (CP 2.3.2.1, Table 2.1).

\[
\begin{align*}
1.4G \\
1.4G + 1.6Q \\
1.4G + 1.6(0.75PQ) \\
1.0G \pm 1.4W \\
1.4G \pm 1.4W \\
1.2G + 1.2Q \pm 1.2W
\end{align*}
\]

These are also the default design load combinations in ETABS whenever the CP-2013 code is used. If roof live load is separately treated or other types of loads are present, other appropriate load combinations should be used. Note that the automatic combination, including pattern live load, is assumed and should be reviewed before using for design.

11.3 Limits on Material Strength

The concrete compressive strength, \(f_{cu}\), should not be less than 20 N/mm\(^2\) (CP 3.1.3). The program does not enforce this limit for flexure and shear design of slabs. The input material strengths are used for design even if they are outside of the limits. It is the user's responsible to use the proper strength values while defining the materials.

11.4 Partial Safety Factors

The design strengths for concrete and reinforcement are obtained by dividing the characteristic strength of the material by a partial safety factor, \(\gamma_m\). The values of \(\gamma_m\) used in the program are listed in the following table, as taken from CP Table 2.2 (CP 2.4.3.2):
Values of $\gamma$ for the Ultimate Limit State

<table>
<thead>
<tr>
<th>Reinforcement</th>
<th>1.15</th>
</tr>
</thead>
<tbody>
<tr>
<td>Concrete in flexure and axial load</td>
<td>1.50</td>
</tr>
<tr>
<td>Concrete shear strength without shear reinforcement</td>
<td>1.25</td>
</tr>
</tbody>
</table>

These factors are incorporated into the design equations and tables in the code, but can be overwritten.

### 11.5 Slab Design

ETABS slab design procedure involves defining sets of strips in two mutually perpendicular directions. The locations of the strips are usually governed by the locations of the slab supports. The axial force, moments and shears for a particular strip are recovered from the analysis (on the basis of the Wood-Armer technique), and a flexural design is carried out based on the ultimate strength design method.

The slab design procedure involves the following steps:

- Design flexural reinforcement
- Design shear reinforcement
- Punching check

#### 11.5.1 Design Flexural Reinforcement

For slabs, ETABS uses either design strips or the finite element based design to calculate the slab flexural reinforcement in accordance with the selected design code. For simplicity, only strip-by-strip design is document in the proceeding sections.

The design of the slab reinforcement for a particular strip is carried out at specific locations along the length of the strip. These locations correspond to the element boundaries. Controlling reinforcement is computed on either side of those element boundaries. The slab flexural design procedure for each load combination involves the following:
- Determine factored axial loads and moments for each slab strip.

- Design flexural reinforcement for the strip.

- These two steps, described in the text that follows, are repeated for every load combination. The maximum reinforcement calculated for the top and bottom of the slab within each design strip, along with the corresponding controlling load combination, is obtained and reported.

11.5.1.1 Determine Factored Moments

In the design of flexural reinforcement of concrete slab, the factored moments for each load combination at a particular design strip are obtained by factoring the corresponding moments for different load cases, with the corresponding load factors.

The slab is then designed for the maximum positive and maximum negative factored moments obtained from all of the load combinations. Calculation of bottom reinforcement is based on positive design strip moments. In such cases, the slab may be designed as a rectangular or flanged slab section. Calculation of top reinforcement is based on negative design strip moments. In such cases, the slab may be designed as a rectangular or inverted flanged slab section.

11.5.1.2 Determine Required Flexural Reinforcement

In the flexural reinforcement design process, the program calculates both the tension and compression reinforcement. Compression reinforcement is added when the applied design moment exceeds the maximum moment capacity of a singly reinforced section. The user has the option of avoiding the compression reinforcement by increasing the effective depth, the width, or the strength of the concrete.

The design procedure is based on the simplified rectangular stress block shown in Figure 11-1 (CP 6.1.2.4(a)), where \( \varepsilon_{c,\text{max}} \) is defined as:

\[
\varepsilon_{c,\text{max}} = \begin{cases} 
0.0035 & \text{if } f_{cu} \leq 60\text{N/mm}^2 \\
0.0035 - 0.00006(f_{cu} - 60)^{1/2} & \text{if } f_{cu} > 60\text{N/mm}^2 
\end{cases}
\]
Furthermore, it is assumed that moment redistribution in the member does not exceed 10% (i.e., $\beta_b \geq 0.9$; CP 6.1.2.4(b)). The code also places a limitation on the neutral axis depth,

$$\frac{x}{d} \leq \begin{cases} 0.5 & \text{for } f_{cu} \leq 45 \text{ N/mm}^2 \\ 0.4 & \text{for } 45 < f_{cu} \leq 70 \text{ N/mm}^2 \\ 0.33 & \text{for } 70 < f_{cu} \leq 100 \text{ N/mm}^2 \end{cases} \quad \text{(CP 6.1.2.4(b))}$$

to safeguard against non-ductile failures (CP 6.1.2.4(b)). In addition, the area of compression reinforcement is calculated assuming that the neutral axis depth remains at the maximum permitted value.

The depth of the compression block is given by:

$$a = \begin{cases} 0.9x & \text{for } f_{cu} \leq 45 \text{ N/mm}^2 \\ 0.8x & \text{for } 45 < f_{cu} \leq 70 \text{ N/mm}^2 \\ 0.72x & \text{for } 70 < f_{cu} \leq 100 \text{ N/mm}^2 \end{cases} \quad \text{(CP 6.1.2.4(a), Fig 6.1)}$$

The design procedure used by ETABS, for both rectangular and flanged sections (L- and T-shaped sections), is summarized in the text that follows. For reinforced concrete design where design ultimate axial compression load does not exceed $(0.1f_{cu}A_g)$ (CP 6.1.2.4(a)), axial force is ignored; hence, all slabs are designed for major direction flexure and shear only. Axial compression greater than $0.1f_{cu}A_g$ and axial tensions are always included in flexural and shear design.

### 11.5.1.2.1 Design of uniform thickness slab

For uniform thickness slab, the limiting moment capacity as a singly reinforced slab, $M_{\text{single}}$, is obtained first for a section. The reinforcing is determined based on whether $M$ is greater than, less than, or equal to $M_{\text{single}}$. See Figure 11-1

Calculate the ultimate limiting moment of resistance of the section as singly reinforced.

$$M_{\text{single}} = Kf_{cu}bd^2,$$ \quad \text{(CP 6.1.2.4(c), Eqn. 6.8)}
ETABS Reinforced Concrete Design

\[ K' = \begin{cases} 
0.156 & \text{for } f_{cu} \leq 45 \text{ N/mm}^2 \\
0.120 & \text{for } 45 < f_{cu} \leq 70 \text{ N/mm}^2 \\
0.094 & \text{for } 70 < f_{cu} \leq 100 \text{ N/mm}^2 
\end{cases} \]

- If \( M \leq M_{\text{single}} \), the area of tension reinforcement, \( A_s \), is obtained from:

\[
A_s = \frac{M}{0.87f_{sz}}, \text{ where } \quad (\text{CP 6.1.2.4(c), Eqn. 6.12})
\]

\[
z = d \left( 0.5 + \sqrt{0.25 - \frac{K}{0.9}} \right) \leq 0.95d \quad (\text{CP 6.1.2.4(c), Eqn. 6.10})
\]

\[
K = \frac{M}{f_{cu}bd^2} \quad (\text{CP 6.1.2.4(c), Eqn. 6.7})
\]

Figure 11-1 Uniform Thickness Slab Design

11 - 8 Slab Design
This reinforcement is to be placed at the bottom if \( M \) is positive, or at the top if \( M \) is negative.

- If \( M > M_{\text{single}} \), compression reinforcement is required and calculated as follows:

\[
A'_{s} = \frac{M - M_{\text{single}}}{\left( f'_{s} - \frac{0.67f_{cu}}{\gamma_{c}} \right)(d - d')}
\]

(CP 6.1.2.4(c), Eqn. 6.15)

where \( d' \) is the depth of the compression reinforcement from the concrete compression face, and

\[
f'_{s} = E_{c}e_{c}\left(1 - \frac{d'}{x}\right) \leq 0.87f_{y}, \quad (\text{CP 6.1.2.4(c)}, \quad 3.2.6, \quad \text{Fig. 3.9})
\]

\[
x = \begin{cases} 
\frac{d - z}{0.45}, & \text{for} \quad f_{cu} \leq 45 \text{N/mm}^2 \\
\frac{d - z}{0.40}, & \text{for} \quad 45 < f_{cu} \leq 70 \text{N/mm}^2 \quad (\text{CP 6.1.2.4(a)}, \quad \text{Fig 6.1, Eqn. 6.11}) \\
\frac{d - z}{0.36}, & \text{for} \quad 70 < f_{cu} \leq 100 \text{N/mm}^2
\end{cases}
\]

\[
z = d \left( 0.5 + \sqrt{0.25 - \frac{K'}{0.9}} \right) \leq 0.95d
\]

(CP 6.1.2.4(c))

The tension reinforcement required for balancing the compression in the concrete and the compression reinforcement is calculated as:

\[
A_{y} = \frac{M_{\text{single}}}{0.87f_{y}z} + \frac{M - M_{\text{single}}}{0.87f_{y}(d - d')}
\]

(CP 6.1.2.4(c))
11.5.1.2.2 Design of nonuniform thickness slab

11.5.1.2.2.1 Flanged Slab Section Under Negative Moment

In designing for a factored negative moment, \( M \) (i.e., designing top reinforcement), the calculation of the reinforcement area is exactly the same as described previously, i.e., no flanged data is used.

11.5.1.2.2.2 Flanged Slab Section Under Positive Moment

With the flange in compression, the program analyzes the section by considering alternative locations of the neutral axis. Initially, the neutral axis is assumed to be located in the flange. On the basis of this assumption, the program calculates the exact depth of the neutral axis. If the stress block does not extend beyond the flange thickness, the section is designed as a uniform thickness slab of width \( b_f \). If the stress block extends beyond the flange depth, the contribution of the web to the flexural strength of the slab is taken into account. See Figure 11-2.

Assuming the neutral axis to lie in the flange, the normalized moment is given by:

\[
K = \frac{M}{f_{cu} b_f d^2}. \quad \text{(CP 6.1.2.4(c), Eqn. 6.7)}
\]

Then the moment arm is computed as:

\[
z = d \left( 0.5 + \sqrt{0.25 - \frac{K}{0.9}} \right) \leq 0.95d, \quad \text{(CP 6.1.2.4(c), Eqn. 6.10)}
\]

the depth of the neutral axis is computed as:

\[
x = \begin{cases} 
\frac{d - z}{0.45}, & \text{for } f_{cu} \leq 45 \text{ N/mm}^2 \\
\frac{d - z}{0.40}, & \text{for } 45 < f_{cu} \leq 70 \text{ N/mm}^2 \\
\frac{d - z}{0.36}, & \text{for } 70 < f_{cu} \leq 100 \text{ N/mm}^2 
\end{cases} \quad \text{(CP 6.1.2.4(c), Fig. 6.1, Eqn. 6.11)}
\]

11 - 10 Slab Design
and the depth of the compression block is given by:

\[
\alpha = \begin{cases} 
0.9x & \text{for } f_{cu} \leq 45 \text{ N/mm}^2 \\
0.8x & \text{for } 45 < f_{cu} \leq 70 \text{ N/mm}^2 \\
0.72x & \text{for } 70 < f_{cu} \leq 100 \text{ N/mm}^2
\end{cases} \quad \text{(CP 6.1.2.4(a), Fig 6.1)}
\]

- If \( a \leq h_f \), the subsequent calculations for \( A_s \) are exactly the same as previously defined for the uniform thickness slab design. However, in that case, the width of the slab is taken as \( b_f \). Compression reinforcement is required when \( K > K' \).

- If \( a > h_f \), the calculation for \( A_s \) has two parts. The first part is for balancing the compressive force from the flange, \( C_f \), and the second part is for balancing the compressive force from the web, \( C_w \), as shown in Figure 11-2.

**Figure 11-2 Nonuniform Thickness Slab Design**

In that case, the ultimate resistance moment of the flange is given by:

\[
M_f = 0.67 \frac{f_{cu}}{\gamma_c} \left( b_f - b_w \right) h_f \left( d - 0.5h_f \right)
\]
The moment taken by the web is computed as:

\[ M_w = M - M_f \]

and the normalized moment resisted by the web is given by:

\[ K_w = \frac{M_w}{f_{cu} b_w d^2} \]

- If \( K_w \leq K' \) (CP 6.1.2.4(c)), the slab is designed as a singly reinforced concrete section. The reinforcement is calculated as the sum of two parts, one to balance compression in the flange and one to balance compression in the web.

\[
A_s = \frac{M_f}{0.87 f_y (d - 0.5 h_f)} + \frac{M_w}{0.87 f_y z}, \text{ where}
\]

\[ z = d \left( 0.5 + \sqrt{0.25 - \frac{K_w}{0.9}} \right) \leq 0.95 d \]

- If \( K_w > K' \), compression reinforcement is required and is calculated as follows:

The ultimate moment of resistance of the web only is given by:

\[ M_{uw} = K f_{cu} b_w d^2 \]

The compression reinforcement is required to resist a moment of magnitude \( M_w - M_{uw} \). The compression reinforcement is computed as:

\[
A'_s = \frac{M_w - M_{uw}}{\left( f_s - \frac{0.67 f_{cu}}{\gamma_c} \right) (d - d')} \]

where, \( d' \) is the depth of the compression reinforcement from the concrete compression face, and

\[ f_s = E_s \varepsilon_c \left( 1 - \frac{d}{\lambda} \right) \leq 0.87 f_y \quad \text{ (CP 6.1.2.4(c), 3.2.6, Fig 3.9)} \]

The area of tension reinforcement is obtained from equilibrium as:

11 - 12 Slab Design
11.5.1.2.2.3 Minimum and Maximum Reinforcement

The minimum flexural tension reinforcement required in each direction of a slab is given by the following limits (CP 9.3.1.1), with interpolation for reinforcement of intermediate strength:

\[
A_s = \frac{1}{0.87 f_y} \left[ \frac{M_f}{d - 0.5h_f} + \frac{M_{uw}}{z} + \frac{M_w - M_{uw}}{d - d'} \right]
\]

\[
z = d \left( 0.5 + \sqrt{0.25 - \frac{K'}{0.9}} \right) \leq 0.95d
\]

In addition, an upper limit on both the tension reinforcement and compression reinforcement has been imposed to be 0.04 times the gross cross-sectional area (CP 9.2.1.3).

11.5.2 Design Slab Shear Reinforcement

The shear reinforcement is designed for each load combination at each station along the design strip. In designing the shear reinforcement for a particular strip, for a particular load combination, at a particular station due to the slab major shear, the following steps are involved (CP 6.1.2.5):

- Determine the shear stress, \( v \).
- Determine the shear stress, \( v_c \), that can be resisted by the concrete.
- Determine the shear reinforcement required to carry the balance.

The following three sections describe in detail the algorithms associated with these steps.
11.5.2.1 Determine Shear Stress

In the design of the slab shear reinforcement, the shear stresses for each load combination at a particular design strip station are obtained by factoring the corresponding shear forces for different load cases, with the corresponding load combination factors:

\[
v = \frac{V}{bd}
\]

(CP 6.1.2.5(a))

The maximum allowable shear stress, \(v_{\text{max}}\), is defined as:

\[
v_{\text{max}} = \min(0.8 \sqrt{f_{\text{cu}}}, 7 \text{ MPa})
\]

(CP 6.1.2.5(a))

11.5.2.2 Determine Concrete Shear Capacity

The shear stress carried by the concrete, \(v_c\), is calculated as:

\[
v'_c = v_c + 0.6 \frac{N V h}{A_c M} \leq v_c \sqrt{1 + \frac{N}{A_c v_c}}
\]

(CP 6.1.2.5(k) , Eqn. 6.22)

\[
v_c = \frac{0.79 k_1 k_2 \left( \frac{100 A_c}{bd} \right)^{3/8} \left( \frac{400}{d} \right)^{1/4}}{\gamma_m}
\]

(CP 6.1.2.5(c), Table 6.3)

\(k_1\) is the enhancement factor for support compression, and is conservatively taken as 1

(CP 6.1.2.5(g))

\[
k_2 = \left( \frac{f_{\text{cu}}}{25} \right)^{3/5}, \quad 1 \leq k_2 \leq \left( \frac{80}{25} \right)^{3/5}
\]

(CP 6.1.2.5(c), Table 6.3)

\[\gamma_m = 1.25\]

(CP 6.1.2.5(c), Table 6.3)

However, the following limitations also apply:

\[
0.15 \leq \frac{100 A_c}{bd} \leq 3,
\]

(CP 6.1.2.5(c), Table 6.3)
\[
\left( \frac{400}{d} \right)^{1/4} \geq 0.67, \quad \text{Members without shear reinforcement}
\]
\[
1.00, \quad \text{Members with shear reinforcement}
\]

\[
\frac{Vh}{M} \leq 1
\]

11.5.2.3 Determine Required Shear Reinforcement

Given \( v, v_c, \) and \( v_{\text{max}} \), the required shear reinforcement is calculated as follows (CP Table 6.2, CP 6.1.2.5(b)):

- Calculate the design average shear stress that can be carried by minimum shear reinforcement, \( v_r \), as:
  \[
  v_r = \begin{cases} 
  0.4 & \text{if} \quad f_{cu} \leq 40\sqrt{\text{f}_{\text{mm}}} \\
  0.4 \left( \frac{f_{cu}}{40} \right)^{1/3} & \text{if} \quad 40 < f_{cu} \leq 80\sqrt{\text{f}_{\text{mm}}} \\
  0.4 \left( \frac{80}{40} \right)^{1/3} & \text{if} \quad f_{cu} > 80\sqrt{\text{f}_{\text{mm}}} 
  \end{cases}
  \]

- If \( v \leq v'_{c} + v_r \), minimum reinforcement is required:
  \[
  \frac{A_s}{s_v} = \frac{v \cdot b}{0.87 f_{\text{yw}}} \]

- If \( v > v'_{c} + v_r \),
  \[
  \frac{A_{yw}}{s_v} = \frac{(v - v'_{c}) \cdot b}{0.87 f_{\text{yw}}} \]

- If \( v > v_{\text{max}} \), a failure condition is declared.

The maximum of all the calculated \( A_s/s_v \) values obtained from each load combination is reported along with the controlling shear force and associated load combination.
The slab shear reinforcement requirements considered by the program are based purely on shear strength considerations. Any minimum stirrup requirements to satisfy spacing and volumetric considerations must be investigated independently of the program by the user.

11.5.3 Check for Punching Shear

The algorithm for checking punching shear is detailed in the section entitled “Slab Punching Shear Check” in the Chapter 1. Only the code-specific items are described in the following sections.

11.5.3.1 Critical Section for Punching Shear

The punching shear is checked on a critical section at a distance of $1.5d$ from the face of the support (CP 6.1.5.7(d)). For rectangular columns and concentrated loads, the critical area is taken as a rectangular area with the sides parallel to the sides of the columns or the point loads (CP 6.1.5.7). Figure 11-3 shows the auto punching perimeters considered by ETABS for the various column shapes. The column location (i.e., interior, edge, corner) and the punching perimeter may be overwritten using the Punching Check Overwrites.

![Figure 11-3 Punching Shear Perimeters](image)

11 - 16 Slab Design
11.5.3.2 Determine Concrete Capacity

The concrete punching shear factored strength is taken as (CP 6.1.5.7(d), Table 6.3):

\[ v_c = \frac{0.79k_1k_2}{\gamma_m} \left( \frac{100A_s}{bd} \right)^{\frac{1}{3}} \left( \frac{400}{d} \right)^{\frac{1}{4}} \]  

(CP 6.1.2.5(d), Table 6.3)

- \( k_1 \) is the enhancement factor for support compression, and is conservatively taken as 1 (CP 6.1.2.5(g), 6.1.5.7(d))

\[ k_2 = \left( \frac{f_{cu}}{25} \right)^{\frac{1}{3}} \]  

1 \( \leq k_2 \leq \left( \frac{80}{25} \right)^{\frac{1}{3}} \) 

(CP 6.1.2.5(c), Table 6.3)

\[ \gamma_m = 1.25 \]  

(CP 2.4.3.2, Table 2.2)

However, the following limitations also apply:

\[ 0.15 \leq \frac{100A_s}{bd} \leq 3, \]  

(CP 6.1.2.5(c), Table 6.3)

\[ \left( \frac{400}{d} \right)^{\frac{1}{4}} \left( \frac{d}{d} \right)^{\frac{1}{4}} \geq \begin{cases} 0.67, & \text{Members without shear reinforcement} \\ 1.00, & \text{Members with shear reinforcement} \end{cases} \]  

(CP 6.1.2.5(c), Table 6.3)

- \( A_s \) = area of tension reinforcement, which is taken as the average tension reinforcement of design strips in Layer A and layer B where Layer A and Layer design strips are in orthogonal directions. When design strips are not present in both orthogonal directions then tension reinforcement is taken as zero in the current implementation.

\[ v \leq \min(0.8\sqrt{f_{cu}}, 7 \text{ MPa}) \]  

(CP 6.1.5.7(b))

\[ f_{cu} \leq 80 \text{ MPa} \text{ (for calculation purpose only)} \]  

(CP Table 6.3)
11.5.3.3 Determine Maximum Shear Stress

Given the punching shear force and the fractions of moments transferred by eccentricity of shear about the bending axis, the nominal design shear stress, \( v_{\text{max}} \), is calculated as:

\[
V_{\text{eff},x} = V \left( f + \frac{1.5M_x}{V_y} \right) \quad \text{(CP 6.1.5.6(b), 6.1.5.6(c))}
\]

\[
V_{\text{eff},y} = V \left( f + \frac{1.5M_y}{V_x} \right) \quad \text{(CP 6.1.5.6(b), 6.1.5.6(c))}
\]

\[
v_{\text{max}} = \max \left( \frac{V_{\text{eff},x}}{u d}, \frac{V_{\text{eff},y}}{u d} \right) \quad \text{(CP 6.1.5.7)}
\]

where,

- \( u \) is the perimeter of the critical section,
- \( x \) and \( y \) are the lengths of the sides of the critical section parallel to the axis of bending,
- \( M_x \) and \( M_y \) are the design moments transmitted from the slab to the column at the connection,
- \( V \) is the total punching shear force, and
- \( f \) is a factor to consider the eccentricity of punching shear force and is taken as

\[
f = \begin{cases} 
1.00 & \text{for interior columns} \\
1.25 & \text{for edge columns} \\
1.25 & \text{for corner columns} 
\end{cases} \quad \text{(CP 6.1.5.6(b), 6.1.5.6(c))}
\]
11.5.3.4 Determine Capacity Ratio
The ratio of the maximum shear stress and the concrete punching shear stress capacity is reported as the punching shear capacity ratio by ETABS. If this ratio exceeds 1.0, punching shear reinforcement is designed as described in the following section.

11.5.4 Design Punching Shear Reinforcement
The use of shear links as shear reinforcement in slabs is permitted, provided that the effective depth of the slab is greater than or equal to 200 mm (CP 6.1.5.7(e)). The use of shear studs is not covered in Hong Kong CP 2013. However, program uses the identical clauses for shear studs when CP 20013 code is selected. If the slab thickness does not meet these requirements, the punching shear reinforcement is not designed and the slab thickness should be increased by the user.

The algorithm for designing the required punching shear reinforcement is used when the punching shear capacity ratio exceeds unity. The Critical Section for Punching Shear and Transfer of Unbalanced Moment as described in the earlier sections remain unchanged. The design of punching shear reinforcement is carried out as described in the subsections that follow.

11.5.4.1 Determine Concrete Shear Capacity
The concrete punching shear stress capacity of a section with punching shear reinforcement is as previously determined for the punching check.

11.5.4.2 Determine Required Shear Reinforcement
The shear stress is limited to a maximum of:

\[ v_{\text{max}} = 2v_c \]  

(CP 6.1.5.7(e))

Given \( v, v_c \), and \( v_{\text{max}} \), the required shear reinforcement is calculated as follows (CP 6.1.5.7(e)).

- If \( v \leq 1.6v_c \),
\[
\frac{A_v}{s} = \left( v - v_c \right) ud \geq \frac{v_ud}{0.87 f_y}, 
\]  (CP 6.1.5.7(e))

- If \(1.6v_c \leq v < 2.0v_c\),

\[
\frac{A_v}{s} = 5\left(0.7v - v_c\right)ud \geq \frac{v_ud}{0.87 f_y}, 
\]  (CP 6.1.5.7(e))

\[
v_r = \begin{cases} 
0.4 \\
0.4 \left(\frac{f_{cu}}{40}\right)^{2/3} \text{ N/mm}^2 
\end{cases} 
\]  (CP 6.1.5.7, Table 6.2)

- If \(v > 2.0v_c\), a failure condition is declared.  (CP 6.1.5.7(e))

If \(v\) exceeds the maximum permitted value of \(v_{\text{max}}\), the concrete section should be increased in size.

### 11.5.4.3 Determine Reinforcement Arrangement

Punching shear reinforcement in the vicinity of rectangular columns should be arranged on peripheral lines, i.e., lines running parallel to and at constant distances from the sides of the column. Figure 11-4 shows a typical arrangement of shear reinforcement in the vicinity of a rectangular interior, edge, and corner column.

The distance between the column face and the first line of shear reinforcement shall not exceed \(d/2\). The spacing between adjacent shear reinforcement in the first line (perimeter) of shear reinforcement shall not exceed \(1.5d\) measured in a direction parallel to the column face (CP 6.1.5.7(f)).

Punching shear reinforcement is most effective near column corners where there are concentrations of shear stress. Therefore, the minimum number of lines of shear reinforcement is 4, 6, and 8, for corner, edge, and interior columns respectively.
11.5.4.4 Determine Reinforcement Diameter, Height, and Spacing

The punching shear reinforcement is most effective when the anchorage is close to the top and bottom surfaces of the slab. The cover of anchors should not be less than the minimum cover specified in CP 4.2.4 plus half of the diameter of the flexural reinforcement.

Punching shear reinforcement in the form of shear studs is generally available in 10-, 12-, 14-, 16-, and 20-millimeter diameters.

When specifying shear studs, the distance, \( s_o \), between the column face and the first peripheral line of shear studs should not be smaller than 0.5\( d \). The spacing between adjacent shear studs, \( g \), at the first peripheral line of studs shall not exceed 1.5\( d \). The limits of \( s_o \) and the spacing, \( s \), between the peripheral lines are specified as:

\[
\begin{align*}
    s_o & \leq 0.5d \\
    s & \leq 0.75d \\
    g & \leq 1.5d
\end{align*}
\]

(\( CP \ 6.1.5.7(f) \))

Stirrups are only permitted when slab thickness is greater than 200 mm (\( CP \ 6.1.5.7(e) \)).
This chapter describes in detail the various aspects of the concrete design procedure that is used by ETABS when the Hong Kong limit state code CP-04 [CP 04], which also incorporates Amendment 1 published in June 2007, is selected. The various notations used in this chapter are listed in Table 12-1. For referencing to the pertinent sections of the Hong Kong code in this chapter, a prefix “CP” followed by the section number is used.

The design is based on user-specified load combinations. The program provides a set of default load combinations that should satisfy the requirements for the design of most building type structures.

English as well as SI and MKS metric units can be used for input. The code is based on Newton-millimeter-second units. For simplicity, all equations and descriptions presented in this chapter correspond to Newton-millimeter-second units unless otherwise noted.

### 12.2 Design Load Combinations

The design load combinations are the various combinations of the load cases for which the structure needs to be designed. The design load combinations are obtained by multiplying the characteristic loads by appropriate partial factors of...
ETABS Reinforced Concrete Design

safety, $\gamma_f$ (CP 2.3.1.3). For CP-04, if a structure is subjected to dead (D), live (L), pattern live (PL), and wind (W) loads, and considering that wind forces are reversible, the following load combinations may need to be considered. (CP 2.3.2.1, Table 2.1).

1. $1.4D$
2. $1.4D + 1.6L$ (CP 2.3.2)
3. $1.4D + 1.6(0.75PL)$ (CP 2.3.2)
4. $1.0D \pm 1.4W$
5. $1.4D \pm 1.4W$ (CP 2.3.2)
6. $1.2D + 1.2L \pm 1.2W$

These are also the default design load combinations in ETABS whenever the CP-04 code is used. If roof live load is separately treated or other types of loads are present, other appropriate load combinations should be used. Note that the automatic combination, including pattern live load, is assumed and should be reviewed before using for design.

12.3 Limits on Material Strength

The concrete compressive strength, $f_{cu}$, should not be less than 20 N/mm² (CP 3.1.3). The program does not enforce this limit for flexure and shear design of slabs. The input material strengths are used for design even if they are outside of the limits. It is the user's responsible to use the proper strength values while defining the materials.

12.4 Partial Safety Factors

The design strengths for concrete and reinforcement are obtained by dividing the characteristic strength of the material by a partial safety factor, $\gamma_m$. The values of $\gamma_m$ used in the program are listed in the following table, as taken from CP Table 2.2 (CP 2.4.3.2):

12 - 4 Limits on Material Strength
Values of $\gamma_m$ for the Ultimate Limit State

<table>
<thead>
<tr>
<th>Reinforcement</th>
<th>1.15</th>

</thead>
<tbody>
<tr>
<td>Concrete in flexure and axial load</td>
<td>1.50</td>
</tr>
<tr>
<td>Concrete shear strength without shear reinforcement</td>
<td>1.25</td>
</tr>
</tbody>
</table>

These factors are incorporated into the design equations and tables in the code, but can be overwritten.

### 12.5 Slab Design

ETABS slab design procedure involves defining sets of strips in two mutually perpendicular directions. The locations of the strips are usually governed by the locations of the slab supports. The axial force, moments and shears for a particular strip are recovered from the analysis (on the basis of the Wood-Armer technique), and a flexural design is carried out based on the ultimate strength design method.

The slab design procedure involves the following steps:

- Design flexural reinforcement
- Design shear reinforcement
- Punching check

#### 12.5.1 Design Flexural Reinforcement

For slabs, ETABS uses either design strips or the finite element based design to calculate the slab flexural reinforcement in accordance with the selected design code. For simplicity, only strip-by-strip design is document in the proceeding sections.

The design of the slab reinforcement for a particular strip is carried out at specific locations along the length of the strip. These locations correspond to the element boundaries. Controlling reinforcement is computed on either side of those element boundaries. The slab flexural design procedure for each load combination involves the following:
- Determine factored axial loads and moments for each slab strip.
- Design flexural reinforcement for the strip.
- These two steps, described in the text that follows, are repeated for every load combination. The maximum reinforcement calculated for the top and bottom of the slab within each design strip, along with the corresponding controlling load combination, is obtained and reported.

12.5.1.1 Determine Factored Moments
In the design of flexural reinforcement of concrete slab, the factored moments for each load combination at a particular design strip are obtained by factoring the corresponding moments for different load cases, with the corresponding load factors.

The slab is then designed for the maximum positive and maximum negative factored moments obtained from all of the load combinations. Calculation of bottom reinforcement is based on positive design strip moments. In such cases, the slab may be designed as a rectangular or flanged slab section. Calculation of top reinforcement is based on negative design strip moments. In such cases, the slab may be designed as a rectangular or inverted flanged slab section.

12.5.1.2 Determine Required Flexural Reinforcement
In the flexural reinforcement design process, the program calculates both the tension and compression reinforcement. Compression reinforcement is added when the applied design moment exceeds the maximum moment capacity of a singly reinforced section. The user has the option of avoiding the compression reinforcement by increasing the effective depth, the width, or the strength of the concrete.

The design procedure is based on the simplified rectangular stress block shown in Figure 12-1 (CP 6.1.2.4(a)), where \( \varepsilon_{c,\text{max}} \) is defined as:

\[
\varepsilon_{c,\text{max}} = \begin{cases} 
0.0035 & \text{if } f_{cu} \leq 60\text{N/mm}^2 \\
0.0035 - 0.00006(f_{cu} - 60)^{\frac{1}{2}} & \text{if } f_{cu} > 60\text{N/mm}^2 
\end{cases}
\]
Furthermore, it is assumed that moment redistribution in the member does not exceed 10% (i.e., $\beta_b \geq 0.9$; CP 6.1.2.4(b)). The code also places a limitation on the neutral axis depth,

$$\frac{x}{d} \leq \begin{cases} 
0.5 & \text{for } f_{cu} \leq 45 \text{ N/mm}^2 \\
0.4 & \text{for } 45 < f_{cu} \leq 70 \text{ N/mm}^2 \\
0.33 & \text{for } 70 < f_{cu} \leq 100 \text{ N/mm}^2 
\end{cases} \quad (\text{CP 6.1.2.4(b)})$$

to safeguard against non-ductile failures (CP 6.1.2.4(b)). In addition, the area of compression reinforcement is calculated assuming that the neutral axis depth remains at the maximum permitted value.

The depth of the compression block is given by:

$$a = \begin{cases} 
0.9x & \text{for } f_{cu} \leq 45 \text{ N/mm}^2 \\
0.8x & \text{for } 45 < f_{cu} \leq 70 \text{ N/mm}^2 \\
0.72x & \text{for } 70 < f_{cu} \leq 100 \text{ N/mm}^2 
\end{cases} \quad (\text{CP 6.1.2.4(a), Fig 6.1})$$

The design procedure used by ETABS, for both rectangular and flanged sections (L- and T-shaped sections), is summarized in the text that follows. For reinforced concrete design where design ultimate axial compression load does not exceed $(0.1f_{cu}A_g)$ (CP 6.1.2.4(a)), axial force is ignored; hence, all slabs are designed for major direction flexure and shear only. Axial compression greater than $0.1f_{cu}A_g$ and axial tensions are always included in flexural and shear design.

### 12.5.1.2.1 Design of uniform thickness slab

For uniform thickness slab, the limiting moment capacity as a singly reinforced section, $M_{\text{single}}$, is obtained first for a section. The reinforcing is determined based on whether $M$ is greater than, less than, or equal to $M_{\text{single}}$. See Figure 12-1

Calculate the ultimate limiting moment of resistance of the section as singly reinforced.

$$M_{\text{single}} = K'f_{cu} bd^2, \text{ where}$$

(CP 6.1.2.4(c))
ETABS Reinforced Concrete Design

\[
K' = \begin{cases} 
0.156 & \text{for } f_{cu} \leq 45 \text{ N/mm}^2 \\
0.120 & \text{for } 45 < f_{cu} \leq 70 \text{ N/mm}^2 \\
0.094 & \text{for } 70 < f_{cu} \leq 100 \text{ N/mm}^2
\end{cases}
\]

- If \( M \leq M_{\text{single}} \), the area of tension reinforcement, \( A_s \), is obtained from:

\[
A_s = \frac{M}{0.87 f_{y} z}, \quad \text{where} \quad (\text{CP 6.1.2.4(c)}
\]

\[
z = d \left( 0.5 + \sqrt{0.25 - \frac{K}{0.9}} \right) \leq 0.95d \quad \text{(CP 6.1.2.4(c))}
\]

\[
K = \frac{M}{f_{cu} bd^2} \quad \text{(CP 6.1.2.4(c))}
\]

---

**Figure 12-1 Uniform Thickness Slab Design**

---

12 - 8 Slab Design
This reinforcement is to be placed at the bottom if $M$ is positive, or at the top if $M$ is negative.

- If $M > M_{\text{single}}$, compression reinforcement is required and calculated as follows:

$$A'_s = \frac{M - M_{\text{single}}}{\left( f'_s - 0.67 f_{cu} \right) (d - d')} \quad \text{(CP 6.1.2.4(c))}$$

where $d'$ is the depth of the compression reinforcement from the concrete compression face, and

$$f'_s = E_s e_c \left( 1 - \frac{d'}{x} \right) \leq 0.87 f_s, \quad \text{(CP 6.1.2.4(c), 3.2.6, Fig. 3.9)}$$

$$x = \begin{cases} 
\frac{d - z}{0.45}, & \text{for } f_{cu} \leq 45 \text{ N/mm}^2 \\
\frac{d - z}{0.40}, & \text{for } 45 < f_{cu} \leq 70 \text{ N/mm}^2 \\
\frac{d - z}{0.36}, & \text{for } 70 < f_{cu} \leq 100 \text{ N/mm}^2 
\end{cases} \quad \text{(CP 6.1.2.4(a), Fig 6.1)}$$

$$z = d \left\{ 0.5 + \sqrt{0.25 - \frac{K'}{0.9}} \right\} \leq 0.95d \quad \text{(CP 6.1.2.4(c))}$$

The tension reinforcement required for balancing the compression in the concrete and the compression reinforcement is calculated as:

$$A_s = \frac{M_{\text{single}}}{0.87 f_{s} z} + \frac{M - M_{\text{single}}}{0.87 f_{s} (d - d')} \quad \text{(CP 6.1.2.4(c))}$$
12.5.1.2.2 Design of nonuniform thickness slab

12.5.1.2.2.1 Flanged Slab Section Under Negative Moment

In designing for a factored negative moment, \( M \) (i.e., designing top reinforcement), the calculation of the reinforcement area is exactly the same as described previously, i.e., no flanged data is used.

12.5.1.2.2.2 Flanged Slab Section Under Positive Moment

With the flange in compression, the program analyzes the section by considering alternative locations of the neutral axis. Initially, the neutral axis is assumed to be located in the flange. On the basis of this assumption, the program calculates the exact depth of the neutral axis. If the stress block does not extend beyond the flange thickness, the section is designed as a uniform thickness slab of width \( b_f \). If the stress block extends beyond the flange depth, the contribution of the web to the flexural strength of the section is taken into account. See Figure 12-2.

Assuming the neutral axis to lie in the flange, the normalized moment is given by:

\[
K = \frac{M}{f_{cu} b_f d^2}.
\]

Then the moment arm is computed as:

\[
z = d \left\{ 0.5 + \sqrt{0.25 - \frac{K}{0.9}} \right\} \leq 0.95d,
\]

the depth of the neutral axis is computed as:

\[
x = \begin{cases} 
\frac{d - z}{0.45}, & \text{for } f_{cu} \leq 45 \text{ N/mm}^2 \\
\frac{d - z}{0.40}, & \text{for } 45 < f_{cu} \leq 70 \text{ N/mm}^2 \\
\frac{d - z}{0.36}, & \text{for } 70 < f_{cu} \leq 100 \text{ N/mm}^2 
\end{cases}
\]

and the depth of the compression block is given by:
If \( a \leq h_f \), the subsequent calculations for \( A_s \) are exactly the same as previously defined for the uniform thickness slab design. However, in that case, the width of the slab is taken as \( b_f \). Compression reinforcement is required when \( K > K' \).

If \( a > h_f \), the calculation for \( A_s \) has two parts. The first part is for balancing the compressive force from the flange, \( C_f \), and the second part is for balancing the compressive force from the web, \( C_w \), as shown in Figure 12-2.

\[
a = \begin{cases} 
0.9x & \text{for } f_{cu} \leq 45 \text{ N/mm}^2 \\
0.8x & \text{for } 45 < f_{cu} < 70 \text{ N/mm}^2 \\
0.72x & \text{for } 70 < f_{cu} \leq 100 \text{ N/mm}^2 
\end{cases}
\] (CP 6.1.2.4(a), Fig 6.1)

\( \text{Figure 12-2 Nonuniform Thickness Slab Design} \)

In that case, the ultimate resistance moment of the flange is given by:

\[
M_f = \frac{0.67 f_{cu}}{\gamma_c} \left( b_f - b_w \right) h_f \left( d - 0.5 h_f \right)
\]

The moment taken by the web is computed as:
ETABS Reinforced Concrete Design

\[ M_w = M - M_f \]

and the normalized moment resisted by the web is given by:

\[ K_w = \frac{M_w}{f_{cu} b_w d^2} \]

- If \( K_w \leq K' \) (CP 6.1.2.4(c)), the slab is designed as a singly reinforced concrete slab. The reinforcement is calculated as the sum of two parts, one to balance compression in the flange and one to balance compression in the web.

\[ A_s = \frac{M_f}{0.87 f_y (d - 0.5h_f)} + \frac{M_w}{0.87 f_y z} \]

\[ z = d \left( 0.5 + \sqrt{0.25 - \frac{K_w}{0.9}} \right) \leq 0.95d \]

- If \( K_w > K' \), compression reinforcement is required and is calculated as follows:

The ultimate moment of resistance of the web only is given by:

\[ M_{uw} = Kf_{cu} b_w d^2 \]

The compression reinforcement is required to resist a moment of magnitude \( M_w - M_{uw} \). The compression reinforcement is computed as:

\[ A_s' = \frac{M_w - M_{uw}}{\left( f_{s}' - 0.67 f_{cu} \right) \left( d - d' \right)} \]

where, \( d' \) is the depth of the compression reinforcement from the concrete compression face, and

\[ f_s = E_s \varepsilon_c \left( 1 - \frac{d}{\gamma_c} \right) \leq 0.87 f_y \]  \hspace{1cm} (CP 6.1.2.4(c), 3.2.6, Fig 3.9)

The area of tension reinforcement is obtained from equilibrium as:
12.5.1.2.2.3 Minimum and Maximum Reinforcement

The minimum flexural tension reinforcement required in each direction of a slab is given by the following limits (CP 9.3.1.1), with interpolation for reinforcement of intermediate strength:

\[
A_s \geq \frac{1}{0.87 f_y} \left[ \frac{M_f}{d - 0.5h_f} + \frac{M_{uw}}{z} + \frac{M_w - M_{uw}}{d - d'} \right]
\]

\[z = d \left( 0.5 + \sqrt{0.25 - \frac{K'}{0.9}} \right) \leq 0.95d\]

In addition, an upper limit on both the tension reinforcement and compression reinforcement has been imposed to be 0.04 times the gross cross-sectional area (CP 9.2.1.3).

12.5.2 Design Slab Shear Reinforcement

The shear reinforcement is designed for each load combination at each station along the design strip. In designing the shear reinforcement for a particular strip, for a particular load combination, at a particular station due to the slab major shear, the following steps are involved (CP 6.1.2.5):

- Determine the shear stress, \( \nu \).
- Determine the shear stress, \( \nu_c \), that can be resisted by the concrete.
- Determine the shear reinforcement required to carry the balance.

The following three sections describe in detail the algorithms associated with these steps.
12.5.2.1 Determine Shear Stress

In the design of the slab shear reinforcement, the shear stresses for each load combination at a particular design strip station are obtained by factoring the corresponding shear forces for different load cases, with the corresponding load combination factors:

\[ \frac{v}{bd} = V \]  

(CP 6.1.2.5(a))

The maximum allowable shear stress, \( v_{\text{max}} \), is defined as:

\[ v_{\text{max}} = \min(0.8 \sqrt{f_{\text{cu}}}, \, 7 \, \text{MPa}) \]  

(CP 6.1.2.5(a))

12.5.2.2 Determine Concrete Shear Capacity

The shear stress carried by the concrete, \( v_c \), is calculated as:

\[ v'_c = v_c + 0.6 \frac{NVh}{A_c M} \leq v_c \sqrt{1 + \frac{N}{A_c v_c}} \]  

(CP 6.1.2.5(k))

\[ v_c = \frac{0.79k_1k_2}{\gamma_m} \left( \frac{100A_c}{bd} \right)^{\frac{3}{4}} \left( \frac{400}{d} \right)^{\frac{1}{4}} \]  

(CP 6.1.2.5(c), Table 6.3)

\( k_1 \) is the enhancement factor for support compression, and is conservatively taken as 1  

(CP 6.1.2.5(g))

\[ k_2 = \left( \frac{f_{\text{cu}}}{25} \right)^{\frac{1}{2}}, \quad 1 \leq k_2 \leq \left( \frac{80}{25} \right)^{\frac{1}{2}} \]  

(CP 6.1.2.5(c), Table 6.3)

\[ \gamma_m = 1.25 \]  

(CP 6.1.2.5(c), Table 6.3)

However, the following limitations also apply:

\[ 0.15 \leq \frac{100A_c}{bd} \leq 3, \]  

(CP 6.1.2.5(c), Table 6.3)

12 - 14 Slab Design
Chapter 12 - Design for Hong Kong CP-04

\[
\left( \frac{400}{d} \right)^{1/4} \geq 0.67, \quad \text{Members without shear reinforcement}
\]

\[
1.00, \quad \text{Members with shear reinforcement}
\]

(CP 6.1.2.5(c), Table 6.3)

\[
\frac{V_h}{M} \leq 1
\]

(CP 6.1.2.5(k))

12.5.2.3 Determine Required Shear Reinforcement

Given \( v, v', \) and \( v_{\text{max}} \), the required shear reinforcement is calculated as follows (CP Table 6.2, CP 6.1.2.5(b)):

- Calculate the design average shear stress that can be carried by minimum shear reinforcement, \( v_r \), as:

\[
v_r = \begin{cases} 
0.4 & \text{if } f_{\text{cu}} \leq 40 \text{ N/mm}^2 \\
0.4 \left( \frac{f_{\text{cu}}}{40} \right)^{1/3} & \text{if } 40 < f_{\text{cu}} \leq 80 \text{ N/mm}^2 \\
0.4 \left( \frac{80}{40} \right)^{1/3} & \text{if } f_{\text{cu}} > 80 \text{ N/mm}^2 
\end{cases}
\]

(CP 6.1.2.5(b), Table 6.2)

- If \( v \leq v' + v_r \), minimum reinforcement is required:

\[
\frac{A_s}{s_y} = \frac{v_r b}{0.87 f_{\text{vy}}}
\]

(CP 6.1.2.5(b))

- If \( v > v' + v_r \),

\[
\frac{A_w}{s_y} = \frac{(v - v') b}{0.87 f_{\text{vy}}}
\]

(CP 6.1.2.5(b))

- If \( v > v_{\text{max}} \), a failure condition is declared.

The maximum of all the calculated \( A_s/s_y \) values obtained from each load combination is reported along with the controlling shear force and associated load combination.
The slab shear reinforcement requirements considered by the program are based purely on shear strength considerations. Any minimum stirrup requirements to satisfy spacing and volumetric considerations must be investigated independently of the program by the user.

12.5.3 Check for Punching Shear

The algorithm for checking punching shear is detailed in the section entitled “Slab Punching Shear Check” in the *Key Features and Terminology* manual. Only the code-specific items are described in the following subsections.

12.5.3.1 Critical Section for Punching Shear

The punching shear is checked on a critical section at a distance of $1.5d$ from the face of the support (CP 6.1.5.7(d)). For rectangular columns and concentrated loads, the critical area is taken as a rectangular area with the sides parallel to the sides of the columns or the point loads (CP 6.1.5.7). Figure 12-3 shows the auto punching perimeters considered by ETABS for the various column shapes. The column location (i.e., interior, edge, corner) and the punching perimeter may be overwritten using the Punching Check Overwrites.

![Figure 12-3 Punching Shear Perimeters](image-url)
12.5.3.2 Determine Concrete Capacity

The concrete punching shear factored strength is taken as (CP 6.1.5.7(d), Table 6.3):

\[
v_c = \frac{0.79k_1k_2\left(\frac{100A_s}{bd}\right)^{\frac{3}{5}}\left(\frac{400}{d}\right)^{\frac{1}{4}}}{\gamma_m}
\]

(CP 6.1.2.5(d), Table 6.3)

\( k_1 \) is the enhancement factor for support compression, and is conservatively taken as 1 (CP 6.1.2.5(g), 6.1.5.7(d))

\[
k_2 = \left(\frac{f_{cu}}{25}\right)^{\frac{3}{5}} 1 \leq k_2 \leq \left(\frac{80}{25}\right)^{\frac{3}{5}}
\]

(CP 6.1.2.5(c), Table 6.3)

\[\gamma_m = 1.25\]

(CP 2.4.3.2, Table 2.2)

However, the following limitations also apply:

\[
0.15 \leq \frac{100A_s}{bd} \leq 3,
\]

(CP 6.1.2.5(c), Table 6.3)

\[
\left(\frac{400}{d}\right)^{\frac{1}{4}} \geq \begin{cases} 0.67, & \text{Members without shear reinforcement} \\ 1.00, & \text{Members with shear reinforcement} \end{cases}
\]

(CP 6.1.2.5(c), Table 6.3)

\( A_s \) = area of tension reinforcement, which is taken as the average tension reinforcement of design strips in Layer A and layer B where Layer A and Layer design strips are in orthogonal directions. When design strips are not present in both orthogonal directions then tension reinforcement is taken as zero in the current implementation.

\[v \leq \min(0.8\sqrt{f_{cu}}, 7 \text{ MPa})\]

(CP 6.1.5.7(b))

\[f_{cu} \leq 80 \text{ MPa (for calculation purpose only)}\]

(CP Table 6.3)
12.5.3.3 Determine Maximum Shear Stress

Given the punching shear force and the fractions of moments transferred by eccentricity of shear about the bending axis, the nominal design shear stress, $v_{\text{max}}$, is calculated as:

$$V_{\text{eff,x}} = V \left( f + 1.5 \frac{M_x}{V_y} \right)$$  \hspace{1cm} \text{(CP 6.1.5.6(b), 6.1.5.6(c))}

$$V_{\text{eff,y}} = V \left( f + 1.5 \frac{M_y}{V_x} \right)$$  \hspace{1cm} \text{(CP 6.1.5.6(b), 6.1.5.6(c))}

$$v_{\text{max}} = \max \left( \frac{V_{\text{eff,x}}}{u d} \right)$$

where, $u$ is the perimeter of the critical section, $x$ and $y$ are the lengths of the sides of the critical section parallel to the axis of bending, $M_x$ and $M_y$ are the design moments transmitted from the slab to the column at the connection, $V$ is the total punching shear force, and $f$ is a factor to consider the eccentricity of punching shear force and is taken as

$$f = \begin{cases} 
1.00 & \text{for interior columns} \\
1.25 & \text{for edge columns} \\
1.25 & \text{for corner columns} 
\end{cases}$$  \hspace{1cm} \text{(CP 6.1.5.6(b), 6.1.5.6(c))}
12.5.3.4 Determine Capacity Ratio

The ratio of the maximum shear stress and the concrete punching shear stress capacity is reported as the punching shear capacity ratio by ETABS. If this ratio exceeds 1.0, punching shear reinforcement is designed as described in the following section.

12.5.4 Design Punching Shear Reinforcement

The use of shear studs as shear reinforcement in slabs is permitted, provided that the effective depth of the slab is greater than or equal to 200 mm (CP 6.1.5.7(e)). If the slab thickness does not meet these requirements, the punching shear reinforcement is not designed and the slab thickness should be increased by the user.

The algorithm for designing the required punching shear reinforcement is used when the punching shear capacity ratio exceeds unity. The Critical Section for Punching Shear and Transfer of Unbalanced Moment as described in the earlier sections remain unchanged. The design of punching shear reinforcement is carried out as described in the subsections that follow.

12.5.4.1 Determine Concrete Shear Capacity

The concrete punching shear stress capacity of a section with punching shear reinforcement is as previously determined for the punching check.

12.5.4.2 Determine Required Shear Reinforcement

The shear stress is limited to a maximum of:

\[ v_{\text{max}} = 2v_c \]  

(CP 6.1.5.7(e))

Given \( v, v_c, \) and \( v_{\text{max}} \), the required shear reinforcement is calculated as follows (CP 6.1.5.7(e)).

- If \( v \leq 1.6v_c \),

\[ \frac{A_v}{s} = \frac{(v - v_c)ud}{0.87f_{yy}} \geq \frac{v_ud}{0.87f_{yy}}, \]  

(CP 6.1.5.7(e))

- If \( 1.6v_c < v < 2.0v_c \),
\[ \frac{A_v}{s} = \frac{5(0.7v - v_c)ud}{0.87 f_{yw}} \geq \frac{v_r ud}{0.87 f_{yw}} \]  
(CP 6.1.5.7(e))

\[ v_r = \begin{cases} 0.4 \\ 0.4 \left( \frac{f_{cu}}{40} \right)^{2/3} \text{ N/mm}^2 \end{cases} \]  
(CP 6.1.5.7, Table 6.2)

- If \( v > 2.0v_c \), a failure condition is declared.  
(CP 6.1.5.7(e))

If \( v \) exceeds the maximum permitted value of \( v_{\text{max}} \), the concrete section should be increased in size.

### 12.5.4.3 Determine Reinforcement Arrangement

Punching shear reinforcement in the vicinity of rectangular columns should be arranged on peripheral lines, i.e., lines running parallel to and at constant distances from the sides of the column. Figure 12-4 shows a typical arrangement of shear reinforcement in the vicinity of a rectangular interior, edge, and corner column.

The distance between the column face and the first line of shear reinforcement shall not exceed \( d/2 \). The spacing between adjacent shear reinforcement in the first line (perimeter) of shear reinforcement shall not exceed 1.5 \( d \) measured in a direction parallel to the column face (CP 6.1.5.7(f)).

Punching shear reinforcement is most effective near column corners where there are concentrations of shear stress. Therefore, the minimum number of lines of shear reinforcement is 4, 6, and 8, for corner, edge, and interior columns respectively.
12.5.4.4 Determine Reinforcement Diameter, Height, and Spacing

The punching shear reinforcement is most effective when the anchorage is close to the top and bottom surfaces of the slab. The cover of anchors should not be less than the minimum cover specified in CP 4.2.4 plus half of the diameter of the flexural reinforcement.

Punching shear reinforcement in the form of shear studs is generally available in 10-, 12-, 14-, 16-, and 20-millimeter diameters.

When specifying shear studs, the distance, \( s_o \), between the column face and the first peripheral line of shear studs should not be smaller than 0.5\( d \). The spacing between adjacent shear studs, \( g \), at the first peripheral line of studs shall not exceed 1.5\( d \). The limits of \( s_o \) and the spacing, \( s \), between the peripheral lines are specified as:

\[
\begin{align*}
s_o &\leq 0.5d \quad \text{(CP 6.1.5.7(f))} \\
s &\leq 0.75d \quad \text{(CP 6.1.5.7(f))} \\
g &\leq 1.5d \quad \text{(CP 6.1.5.7(f))}
\end{align*}
\]

Stirrups are only permitted when slab thickness is greater than 200 mm (CP 6.1.5.7(e)).
Chapter 13
Design for IS 456-2000

This chapter describes in detail the various aspects of the concrete design procedure that is used by ETABS when the Indian Code IS 456-2000 [IS 2000] is selected. Various notations used in this chapter are listed in Table 13-1. For referencing to the pertinent sections of the Indian code in this chapter, a prefix “IS” followed by the section number is used.

The design is based on user-specified load combinations. The program provides a set of default load combinations that should satisfy the requirements for the design of most building type structures.

English as well as SI and MKS metric units can be used for input. The code is based on Newton-millimeter-second units. For simplicity, all equations and descriptions presented in this chapter correspond to Newton-millimeter-second units unless otherwise noted.

### 13.2 Design Load Combinations

The design load combinations are the various combinations of the load cases for which the structure needs to be designed. For IS 456-2000, if a structure is subjected to dead (D), live (L), pattern live (PL), snow (S), wind (W), and earthquake (E) loads, and considering that wind and earthquake forces are reversible, the following load combinations may need to be considered (IS 36.4, Table 18):

1. $1.5D$                                
2. $1.5D + 1.5L$                          
3. $1.5D + 1.5S$                          
4. $1.5D + 1.5(0.75 \text{ PL})$         
5. $1.5D \pm 1.5W$                        
6. $0.9D \pm 1.5W$                        
7. $1.2D + 1.2L \pm 1.2W$                
8. $1.5D + 1.5L \pm 1.0W$                
9. $1.5D \pm 1.5E$                        
10. $0.9D \pm 1.5E$                       
11. $1.2D + 1.2L \pm 1.2E$              
12. $1.5D + 1.5L \pm 1.0E$              

(IS 36.4.1)
1.5D + 1.5L + 1.5S
1.2D + 1.2S ± 1.2W
1.2D + 1.2L + 1.2S ± 1.2W
1.2D + 1.2S ± 1.2E
1.2D + 1.2L + 1.2S ± 1.2E

(IS 36.4.1)

These are also the default design load combinations in ETABS whenever the IS 456-2000 code is used. If roof live load is treated separately or other types of loads are present, other appropriate load combinations should be used.

13.3 Partial Safety Factors

The design strength for concrete and reinforcement is obtained by dividing the characteristic strength of the material by a partial safety factor, $\gamma_m$. The values of $\gamma_m$ used in the program are as follows:

Partial safety factor for reinforcement, $\gamma_r = 1.15$  
(IS 36.4.2.1)

Partial safety factor for concrete, $\gamma_c = 1.5$  
(IS 36.4.2.1)

These factors are already incorporated into the design equations and tables in the code. These values can be overwritten; however, caution is advised.

13.4 Slab Design

ETABS slab design procedure involves defining sets of strips in two mutually perpendicular directions. The locations of the strips are usually governed by the locations of the slab supports. The axial force, moments and shears for a particular strip are recovered from the analysis (on the basis of the Wood-Armer technique), and a flexural design is carried out based on the ultimate strength design method.

The slab design procedure involves the following steps:

- Design flexural reinforcement
- Design shear reinforcement
- Punching check
13.4.1 Design Flexural Reinforcement

For slabs, ETABS uses either design strips or the finite element based design to calculate the slab flexural reinforcement in accordance with the selected design code. For simplicity, only strip-by-strip design is document in the proceeding sections.

The design of the slab reinforcement for a particular strip is carried out at specific locations along the length of the strip. These locations correspond to the element boundaries. Controlling reinforcement is computed on either side of those element boundaries. The slab flexural design procedure for each load combination involves the following:

- Determine factored axial loads and moments for each slab strip.
- Design flexural reinforcement for the strip.
- These two steps, described in the text that follows, are repeated for every load combination. The maximum reinforcement calculated for the top and bottom of the slab within each design strip, along with the corresponding controlling load combination, is obtained and reported.

13.4.1.1 Determine Factored Moments

In the design of flexural reinforcement of concrete slab, the factored moments for each load combination at a particular design strip are obtained by factoring the corresponding moments for different load cases, with the corresponding load factors.

The slab is then designed for the maximum positive and maximum negative factored moments obtained from all of the load combinations. Calculation of bottom reinforcement is based on positive design strip moments. In such cases, the slab may be designed as a rectangular or flanged slab section. Calculation of top reinforcement is based on negative design strip moments. In such cases, the slab may be designed as a rectangular or inverted flanged slab section.

13.4.1.2 Determine Required Flexural Reinforcement

In the flexural reinforcement design process, the program calculates both the tension and compression reinforcement. Compression reinforcement is added when the applied design moment exceeds the maximum moment capacity of a singly reinforced section. The user has the option of avoiding compression
reinforcement by increasing the effective depth, the width, or the strength of the concrete.

The design procedure is based on the simplified parabolic stress block shown in Figure 13-1 (IS 38.1). The area of the stress block, $c$, and the depth of the center of the compressive force from the extreme compression fiber, $a$, are taken as

\[ c = \alpha f_{ck} x_u \]  
\[ a = \beta x_u \]  

where $x_u$ is the depth of the neutral axis, and $\alpha$ and $\beta$ are taken as:

\[ \alpha = 0.36 \]  
\[ \beta = 0.42 \]  

where $\alpha$ is the reduction factor to account for sustained compression and the partial safety factor for concrete and is generally taken to be 0.36 for the assumed parabolic stress block (IS 38.1). The $\beta$ factor considers the depth to the center of the compressive force.
Furthermore, it is assumed that moment redistribution in the member does not exceed the code-specified limiting value. The code also places a limitation on the neutral axis depth, as shown in the following table, to safeguard against non-ductile failures (IS 38.1). ETABS uses interpolation between these three values.

<table>
<thead>
<tr>
<th>$f_y$ (MPa)</th>
<th>$x_{u,\text{max}}/d$</th>
</tr>
</thead>
<tbody>
<tr>
<td>250</td>
<td>0.53</td>
</tr>
<tr>
<td>415</td>
<td>0.48</td>
</tr>
<tr>
<td>500</td>
<td>0.46</td>
</tr>
</tbody>
</table>

When the applied moment exceeds the moment capacity of the slab as a singly reinforced section, the area of compression reinforcement is calculated assuming that the neutral axis depth remains at the maximum permitted value. The maximum fiber compression is taken as:

$$\varepsilon_{c,\text{max}} = 0.0035$$  \hspace{1cm} (IS 38.1)

The design procedure used by ETABS, for both rectangular and flanged sections (L- and T-shaped sections), is summarized in the subsections that follow. It is assumed that the design ultimate axial force can be neglected; hence all slabs are designed for major direction flexure and shear only.

### 13.4.1.3 Design of uniform thickness slab

For uniform thickness slab, the limiting depth of the neutral axis, $x_{u,\text{max}}$, and the moment capacity as a singly reinforced section, $M_{\text{single}}$, are obtained first. The reinforcement area is determined based on whether $M_y$ is greater than, less than, or equal to $M_{\text{single}}$.

- **Calculate the limiting depth of the neutral axis.**

$$x_{u,\text{max}} = \begin{cases} 
0.53 & \text{if } f_y \leq 250 \text{ MPa} \\
0.53 - 0.05 \frac{f_y - 250}{165} & \text{if } 250 < f_y \leq 415 \text{ MPa} \\
0.48 - 0.02 \frac{f_y - 415}{85} & \text{if } 415 < f_y \leq 500 \text{ MPa} \\
0.46 & \text{if } f_y \geq 500 \text{ MPa}
\end{cases}$$  \hspace{1cm} (IS 38.1)

- **Calculate the limiting ultimate moment of resistance as a singly reinforced section.**
Chapter 13 - Design for IS 456-2000

\[ M_{\text{single}} = \alpha \frac{x_{u, \text{max}}}{d} \left( 1 - \beta \frac{x_{u, \text{max}}}{d} \right) bd^2 f_{ck} \]  
(IS G-1.1)

- Calculate the depth of the neutral axis as:

\[ \frac{x_u}{d} = \frac{1 - \sqrt{1 - 4\beta m}}{2\beta} \]

where the normalized design moment, \( m \), is given by

\[ m = \frac{M_u}{bd^2 \sigma_f f_{ck}} \]

- If \( M_u \leq M_{\text{single}} \) the area of tension reinforcement, \( A_s \), is obtained from

\[ A_s = \frac{M_u}{(f_y / \gamma_s) z}, \quad \text{where} \quad z = d \left( 1 - \beta \frac{x_u}{d} \right). \]  
(IS G-1.1)

This reinforcement is to be placed at the bottom if \( M_u \) is positive, or at the top if \( M_u \) is negative.

- If \( M_u > M_{\text{single}} \), the area of compression reinforcement, \( A'_c \), is given by:

\[ A'_c = \frac{M_u - M_{\text{single}}}{(f_{sc} - 0.67f_{ck} \gamma_m)(d - d')} \]  
(IS G-1.2)

where \( d' \) is the depth of the compression reinforcement from the concrete compression face, and

\[ f_{sc} = \varepsilon_{c, \text{max}} E_s \left[ 1 - \frac{d'}{x_{u, \text{max}}} \right] \leq \frac{f_y}{\gamma_s} \]  
(IS G-1.2)

The required tension reinforcement is calculated as:
\[
A_s = \frac{M_{\text{single}}}{(f_s/\gamma_s)z} + \frac{M_u - M_{\text{single}}}{(f_s/\gamma_s)(d - d')}, \quad \text{where (IS G-1.2)}
\]
\[
z = d \left(1 - \beta \frac{x_{u,\text{max}}}{d}\right) \quad \text{(IS 38.1)}
\]

\(A_s\) is to be placed at the bottom and \(A'_s\) is to be placed at the top if \(M_u\) is positive, and vice versa if \(M_u\) is negative.

13.4.1.4  Design of nonuniform thickness slab

13.4.1.4.1  Flanged Slab Section Under Negative Moment
In designing for a factored negative moment, \(M_u\) (i.e., designing top reinforcement), the calculation of the reinforcement area is exactly the same as described previously, i.e., no flanged data is used.

13.4.1.4.2  Flanged Slab Section Under Positive Moment
With the flange in compression, the program analyzes the section by considering alternative locations of the neutral axis. Initially the neutral axis is assumed to be located within the flange. On the basis of this assumption, the program calculates the depth of the neutral axis. If the stress block does not extend beyond the flange thickness, the section is designed as a uniform thickness slab of width \(b_f\). If the stress block extends beyond the flange depth, the contribution of the web to the flexural strength of the slab is taken into account. See Figure 13-2.
Assuming the neutral axis lies in the flange, the depth of the neutral axis is calculated as:

\[ x_u = \frac{1 - \sqrt{1 - 4\beta m}}{2\beta} \]

where the normalized design moment, \( m \), is given by

\[ m = \frac{M_u}{b_f d^2 \alpha f_{ck}} \]

- If \( \left( \frac{x_u}{d} \right) \leq \left( \frac{D_f}{d} \right) \), the neutral axis lies within the flange and the subsequent calculations for \( A_s \) are exactly the same as previously defined for the uniform thickness slab design (IS G-2.1). However, in this case, the width of the slab is taken as \( b_f \). Compression reinforcement is required when \( M_u > M_{single} \).

- If \( \left( \frac{x_u}{d} \right) > \left( \frac{D_f}{d} \right) \), the neutral axis lies below the flange and the calculation for \( A_s \) has two parts. The first part is for balancing the compressive force from the
ETABS Reinforced Concrete Design

flange, $C_f$ and the second part is for balancing the compressive force from the web, $C_w$, as shown in Figure 13-2.

– Calculate the ultimate resistance moment of the flange as:

$$M_f = 0.45 f_{ck} \left( b_f - b_w \right) y_f \left( d - \frac{y_f}{2} \right)$$  \hspace{1cm} \text{(IS G-2.2)}$$

where $y_f$ is taken as:

$$y_f = \begin{cases} D_f & \text{if } D_f \leq 0.2d \\ 0.15x_u + 0.65D_f & \text{if } D_f > 0.2d \end{cases}$$  \hspace{1cm} \text{(IS G-2.2)}$$

– Calculate the moment taken by the web as

$$M_w = M_u - M_f.$$  

– Calculate the limiting ultimate moment of resistance of the web for tension reinforcement as:

$$M_{u,\text{single}} = \alpha f_{ck} b_s d^2 \frac{x_{u,\text{max}}}{d} \left[ 1 - \beta \frac{x_{u,\text{max}}}{d} \right]$$  \hspace{1cm} \text{where} \hspace{1cm} \text{(IS G-1.1)}$$

$$x_{u,\text{max}} = \begin{cases} 0.53 & \text{if } f_y \leq 250 \text{ MPa} \\ 0.53 - 0.05 \frac{f_y - 250}{165} & \text{if } 250 < f_y \leq 415 \text{ MPa} \\ 0.48 - 0.02 \frac{f_y - 415}{85} & \text{if } 415 < f_y \leq 500 \text{ MPa} \\ 0.46 & \text{if } f_y \geq 500 \text{ MPa} \end{cases}$$  \hspace{1cm} \text{(IS 38.1)}$$

- If $M_u \leq M_{u,\text{single}}$, the slab is designed as a singly reinforced concrete slab. The area of reinforcement is calculated as the sum of two parts, one to balance compression in the flange and one to balance compression in the web.

$$A_s = \frac{M_f}{\left( f_y/\gamma_s \right) \left( d - 0.5y_f \right)} + \frac{M_w}{\left( f_y/\gamma_s \right) z},$$  \hspace{1cm} \text{where} \hspace{1cm} \text{13 - 12 Slab Design}$$
\[ z = d \left\{ 1 - \beta \frac{x_u}{d} \right\} \]

\[ x_u = \frac{1 - \sqrt{1 - 4\beta m}}{2\beta} \]

\[ m = \frac{M_w}{b_w d^2 \alpha f_{ck}} \]

- If \( M_w > M_{w,\text{single}} \), the area of compression reinforcement, \( A'_{ys} \), is given by:

\[ A'_{ys} = \frac{M_w - M_{w,\text{single}}}{\left( f'_s - \frac{0.67 f_{ck}}{\gamma_m} \right) (d - d')} \]

where \( d' \) is the depth of the compression reinforcement from the concrete compression face, and

\[ f_{sc} = E_s \varepsilon_{c,\text{max}} \left[ 1 - \frac{d'}{x_{u,\text{max}}} \right] \leq \frac{f_s}{\gamma_s} \quad \text{(IS G-1.2)} \]

The required tension reinforcement is calculated as:

\[ A_s = \frac{M_f}{\left( f'_s / \gamma_s \right)(d - 0.5y_f)} + \frac{M_{w,\text{single}}}{f'_s / \gamma_s}z + \frac{M_w - M_{w,\text{single}}}{f'_s / \gamma_s}(d - d') \]

\[ z = d \left\{ 1 - \beta \frac{x_{u,\text{max}}}{d} \right\} \]

### 13.4.1.5 Minimum and Maximum Reinforcement

The minimum flexural tension reinforcement required for each direction of a slab is given by the following limits (IS 26.5.2):

\[ A_s \leq \begin{cases} 0.0015bD & \text{if } f_y < 415 \text{ MPa} \\ 0.0012bD & \text{if } f_y \geq 415 \text{ MPa} \end{cases} \quad \text{(IS 26.5.2.1)} \]
In addition, an upper limit on both the tension reinforcement and compression reinforcement has been imposed to be 0.04 times the gross cross-sectional area (IS 26.5.1.1).

13.4.2 Design Slab Shear Reinforcement

The shear reinforcement is designed for each load combination at each station along the design strip. In designing the shear reinforcement for a particular strip, for a particular load combination, at a particular station due to the slab major shear, the following steps are involved (IS 40.1):

- Determine the design shear stress
- Determine the shear stress that can be resisted by the concrete
- Determine the shear reinforcement required to carry the balance

Determine the design nominal shear stress as follows.

- For prismatic sections
  \[ \tau_v = \frac{V_u}{b d} \]  
  (IS 40.1)

- For non-prismatic sections (slab with varying depth)
  \[ \tau_v = \frac{V_u \pm M_u \tan \beta}{d \tan \beta} \]  
  (IS 40.1.1)

\( \beta = \) angle between the top and bottom edges of the slab

\( M_u \) is the moment at the section, and the negative sign is considered when the numerical value of the moment increases in the same direction as the depth, \( d \), and the positive sign is considered when the numerical value of the moment decreases in the same direction as the depth increases.

\[ \tau_v \leq \tau_{c,\text{max}} \]  
  (IS 40.2.3, Table 20)

The maximum nominal shear stress, \( \tau_{c,\text{max}} \) is given in IS Table 20 as follows:

13 - 14 Slab Design
Chapter 13 - Design for IS 456-2000

<table>
<thead>
<tr>
<th>Concrete Grade</th>
<th>M15</th>
<th>M20</th>
<th>M25</th>
<th>M30</th>
<th>M35</th>
<th>M40</th>
</tr>
</thead>
<tbody>
<tr>
<td>$\tau_{c,\text{max}}$ (MPa)</td>
<td>2.5</td>
<td>2.8</td>
<td>3.1</td>
<td>3.5</td>
<td>3.7</td>
<td>4.0</td>
</tr>
</tbody>
</table>

The maximum nominal shear stress, $\tau_{c,\text{max}}$, is computed using linear interpolation for concrete grades between those indicated in IS Table 20.

Determine the design shear stress that can be carried by the concrete, as:

$$\tau_{cd} = k \delta \lambda \tau_c,$$

where $k$ is the enhancement factor for the depth of the section, taken as 1.0 for slabs, and is computed as follows for other slabs:

$$k = 1$$

$\delta$ is the enhancement factor for compression and is given as:

$$\delta = \begin{cases} 
1 + 3 \frac{P_u}{A_f f_{ck}} & \text{if } P_u > 0, \text{ Under Compression} \\
1 & \text{if } P_u \leq 0, \text{ Under Tension}
\end{cases}$$

$\delta$ is always taken as 1

$\lambda$ is the factor for light-weight concrete, and

$\tau_c$ is the basic design shear strength for concrete, which is given by:

$$\tau_c = 0.64 \left( \frac{100 A_s}{bd} \right)^{\frac{1}{3}} \left( \frac{f_{ck}}{25} \right)^{\frac{1}{4}}$$

The preceding expression approximates IS Table 19. It should be noted that the value of $\gamma_c$ has already been incorporated in IS Table 19 (see note in IS 36.4.2.1). The following limitations are enforced in the determination of the design shear strength as is the case in the Table.

$$0.15 \leq \frac{100 A_s}{bd} \leq 3$$

(IS 40.2.1, Table 19)
\[ f'_{ck} \leq 40 \text{ MPa (for calculation purpose only)} \quad \text{(IS 40.2.1, Table 19)} \]

Determine required shear reinforcement:

- **If** \( \tau_v \leq \tau_{cd} + 0.4 \),

  \[ \frac{A_{sv}}{s_v} = \frac{0.4 b}{0.87 f'_y} \quad \text{(IS 40.3, 26.5.1.6)} \]

- **If** \( \tau_{cd} + 0.4 < \tau_v \leq \tau_{c,\text{max}} \),

  \[ \frac{A_{sv}}{s_v} = \frac{(\tau_v - \tau_{cd}) b}{0.87 f'_y} \quad \text{(IS 40.4(a))} \]

  \[ \frac{A_{sv}}{s_v} \geq \frac{0.4b}{0.87 f'_y} \quad \text{(IS 40.4(a))} \]

- **If** \( \tau_v > \tau_{c,\text{max}} \), a failure condition is declared. \quad \text{(IS 40.2.3)}

In calculating the shear reinforcement, a limit is imposed on the \( f'_y \) as:

\[ f'_y \leq 415 \text{ MPa} \quad \text{(IS 40.4)} \]

The maximum of all of the calculated \( A_{sv}/s_v \) values, obtained from each load combination, is reported along with the controlling shear force and associated load combination.

The slab shear reinforcement requirements considered by the program are based purely on shear strength considerations. Any minimum stirrup requirements to satisfy spacing and volumetric considerations must be investigated independently of the program by the user.

**13.4.3 Check for Punching Shear**

The algorithm for checking punching shear is detailed in the section entitled “Slab Punching Shear Check” in the Chapter 1. Only the code-specific items are described in the following sections.
13.4.3.1 Critical Section for Punching Shear

The punching shear is checked on a critical section at a distance of \( d/2 \) from the face of the support (IS 31.6.1). For rectangular columns and concentrated loads, the critical area is taken as a rectangular area with the sides parallel to the sides of the columns or the point loads (IS 31.6.1). Figure 13-3 shows the auto punching perimeters considered by ETABS for the various column shapes. The column location (i.e., interior, edge, corner), and the punching perimeter may be overwritten using the Punching Check Overwrites.

\[
\alpha = \frac{1}{1 + (2/3) \sqrt{a_1/a_2}} \quad \text{(IS 31.3.3)}
\]

13.4.3.2 Transfer of Unbalanced Moment

The fraction of unbalanced moment transferred by flexure is taken to be \( \alpha M_u \) and the fraction of unbalanced moment transferred by eccentricity of shear is taken to be \( (1 - \alpha) M_u \) (IS 31.6.2.2), where:

\[
\alpha = \frac{1}{1 + (2/3) \sqrt{a_1/a_2}}
\]
and $a_1$ is the width of the critical section measured in the direction of the span and $a_2$ is the width of the critical section measured in the direction perpendicular to the span.

### 13.4.3.3 Determine Concrete Capacity

The concrete punching shear factored strength is taken as:

$$v_c = k_s \tau_c$$  
(IS 31.6.3.1)

$$k_s = 0.5 + \beta_c \leq 1.0$$  
(IS 31.6.3.1)

$$\tau_c = 0.25 \sqrt{f_{ck}}$$  
(IS 31.6.3.1)

$\beta_c$ = ratio of the minimum to the maximum dimensions of the support section.

### 13.4.3.4 Determine Maximum Shear Stress

Given the punching shear force and the fractions of moments transferred by eccentricity of shear about the two axes, the shear stress is computed assuming linear variation along the perimeter of the critical section.

$$v_u = \frac{V_U}{b_0 d} + \frac{\gamma V_2 [M_{U_2} - V_U (y_2 - y_1)] [I_{23} (y_4 - y_1) - I_{23} (x_4 - x_1)]}{I_{22} I_{33} - I_{23}^2}$$  
$$\frac{\gamma V_3 [M_{U_3} - V_U (x_3 - x_1)] [I_{22} (x_4 - x_1) - I_{23} (y_4 - y_3)]}{I_{22} I_{33} - I_{23}^2}$$  

Eq. 1

$$I_{22} = \sum_{sides = 1}^{n} T_{22}$$, where "sides" refers to the sides of the critical section for punching shear  

Eq. 2

$$I_{33} = \sum_{sides = 1}^{n} T_{33}$$, where "sides" refers to the sides of the critical section for punching shear  

Eq. 3

$$I_{23} = \sum_{sides = 1}^{n} T_{23}$$, where "sides" refers to the sides of the critical section for punching shear  

Eq. 4
Chapter 13 - Design for IS 456-2000

Figure 13-4 Shear Stress Calculations at Critical Sections

The equations for $\bar{T}_{22}$, $\bar{T}_{33}$ and $\bar{T}_{23}$ are different depending on whether the side of the critical section for punching shear being considered is parallel to the 2-axis or parallel to the 3-axis. Refer to Figures 13-4.

$$\bar{T}_{22} = Ld(y_2 - y_3)^2$$, for side of critical section parallel to 2-axis

Eq. 5a

$$\bar{T}_{22} = \frac{Ld^3}{12} + \frac{dL^3}{12} + Ld(y_2 - y_3)^2$$, for side of critical section parallel to 3-axis

Eq. 5b

$$\bar{T}_{33} = \frac{Ld^3}{12} + \frac{dL^3}{12} + Ld(x_2 - x_3)^2$$, for side of critical section parallel to 2-axis

Eq. 6a
ETABS Reinforced Concrete Design

\[
T_{33} = Ld(x_2 - x_3)^2, \text{ for side of critical section parallel to 3-axis} \quad \text{Eq. 6b}
\]

\[
T_{23} = Ld(x_2 - x_3)(y_2 - y_3), \text{ for side of critical section parallel to 2-axis or 3-axis} \quad \text{Eq. 7}
\]

**NOTE:** \( T_{23} \) is explicitly set to zero for corner condition.

where,

- \( b_0 \) = Perimeter of critical section for punching shear
- \( d \) = Effective depth at critical section for punching shear based on the average of \( d \) for the 2 direction and \( d \) for the 3 direction
- \( I_{22} \) = Moment of inertia of critical section for punching shear about an axis that is parallel to the local 2-axis
- \( I_{33} \) = Moment of inertia of critical section for punching shear about an axis that is parallel to the local 3-axis
- \( I_{23} \) = Product of inertia of critical section for punching shear with respect to the 2 and 3 planes
- \( L \) = Length of side of critical section for punching shear currently being considered
- \( M_{U2} \) = Moment about line parallel to 2-axis at center of column (positive in accordance with the right-hand rule)
- \( M_{U3} \) = Moment about line parallel to 3-axis at center of column (positive in accordance with the right-hand rule)
- \( v_U \) = Punching shear stress
- \( V_U \) = Shear at center of column (positive upward)
- \( x_1, y_1 \) = Coordinates of column centroid
- \( x_2, y_2 \) = Coordinates of center of one side of critical section for punching shear
- \( x_3, y_3 \) = Coordinates of centroid of critical section for punching shear
13.4.3.5 Determine Capacity Ratio

The ratio of the maximum shear stress and the concrete punching shear stress capacity is reported as the punching shear capacity ratio by ETABS. If this ratio exceeds 1.0, punching shear reinforcement is designed as described in the following section.

13.4.4 Design Punching Shear Reinforcement

The use of shear studs as shear reinforcement in slabs is permitted.

The algorithm for designing the required punching shear reinforcement is used when the punching shear capacity ratio exceeds unity. The Critical Section for Punching Shear and Transfer of Unbalanced Moment as described in the earlier sections remain unchanged. The design of punching shear reinforcement is completed as described in the subsections that follow.

13.4.4.1 Determine Concrete Shear Capacity

The concrete punching shear stress capacity of a section with punching shear reinforcement is as previously determined, but limited to:

\[ v_c \leq 1.5 \tau_c \]  
(IS 31.6.3.2)

13.4.4.2 Determine Required Shear Reinforcement

The shear force is limited to a maximum of:

\[ V_{\text{max}} = 0.5 \tau_c b_s d \]  
(IS 31.6.3.2)

Given \( V_u \), \( V_c \), and \( V_{\text{max}} \), the required shear reinforcement is calculated as follows (IS 31.6.3.2).

\[ A_v = \frac{(V_u - 0.5V_c)S}{0.87 f_y d} \]  
(IS 31.6.3.2, 40.4(a))
• If $V_u > V_{\text{max}}$, a failure condition is declared. (IS 31.6.3.2)

• If $V_u$ exceeds the maximum permitted value of $V_{\text{max}}$, the concrete section should be increased in size.

13.4.4.3 Determine Reinforcement Arrangement

Punching shear reinforcement in the vicinity of rectangular columns should be arranged on peripheral lines, i.e., lines running parallel to and at constant distances from the sides of the column. Figure 13-5 shows a typical arrangement of shear reinforcement in the vicinity of a rectangular interior, edge, and corner column.

The distance between the column face and the first line of shear reinforcement shall not exceed $d/2$. The spacing between adjacent shear reinforcement in the first line (perimeter) of shear reinforcement shall not exceed $2d$ measured in a direction parallel to the column face.

Punching shear reinforcement is most effective near column corners where there are concentrations of shear stress. Therefore, the minimum number of lines of shear reinforcement is 4, 6, and 8, for corner, edge, and interior columns respectively.
13.4.4.4 Determine Reinforcement Diameter, Height, and Spacing

The punching shear reinforcement is most effective when the anchorage is close to the top and bottom surfaces of the slab. The cover of anchors should not be less than the minimum cover specified in IS 26.4 plus half of the diameter of the flexural reinforcement.

When specifying shear studs, the distance, \( s_o \), between the column face and the first peripheral line of shear studs should not be smaller than 0.5\( d \). The spacing between adjacent shear studs, \( g \), at the first peripheral line of studs shall not exceed 2\( d \). The limits of \( s_o \) and the spacing, \( s \), between the peripheral lines are specified as:

\[
s_o \leq 0.5d
\]

\[
s \leq 0.5d
\]

\[
g \leq 2d
\]
Chapter 14
Design for Italian NTC 2008

This chapter describes in detail the various aspects of the concrete design procedure that is used by ETABS when the Italian code NTC2008 [D.M. 14/01/2008] is selected. For the load combinations, reference is also made to NTC2008. Various notations used in this chapter are listed in Table 14-1.

The design is based on user-specified loading combinations. However, the program provides a set of default load combinations that should satisfy requirements for the design of most building type structures.

English as well as SI and MKS metric units can be used for input. The code is based on Newton-millimeter-second units. For simplicity, all equations and descriptions presented in this chapter correspond to Newton-millimeter-second units unless otherwise noted.

14.2 Design Load Combinations

The design load combinations are the various combinations of the load cases for which the structure needs to be checked. NTC2008 allows load combinations to be defined based on NTC2008 Equation 2.5.1.

\[
\sum_{j=1}^{n} \gamma_{G1,j} G_{1,k,j} + \sum_{l=1}^{m} \gamma_{G2,l} G_{2,k,l} + P + \gamma_{Q1} Q_{k,1} + \sum_{i=1}^{p} \gamma_{Q,i} \psi_{0,i} Q_{k,i} \quad \text{(Eq. 2.5.1)}
\]

Load combinations considering seismic loading are automatically generated based on NTC2008 Equation 2.5.5.

\[
\sum_{j=1}^{n} G_{1,k,j} + \sum_{l=1}^{m} G_{2,k,l} + P + E + \sum_{i=1}^{p} \psi_{2,i} Q_{k,i} \quad \text{(Eq. 2.5.5)}
\]

For both sets of load combinations, the variable values are defined in the list that follows.

\[
\begin{align*}
\gamma_{G1,\text{sup}} &= 1.30 \quad \text{(NTC2008 Table 2.6.1)} \\
\gamma_{G1,\text{inf}} &= 1.00 \quad \text{(NTC2008 Table 2.6.1)} \\
\gamma_{G2,\text{sup}} &= 1.50 \quad \text{(NTC2008 Table 2.6.1)} \\
\gamma_{G2,\text{inf}} &= 0.00 \quad \text{(NTC2008 Table 2.6.1)}
\end{align*}
\]
Chapter 14 - Design for Italian NTC 2008

\[
\gamma_{Q,1,\text{sup}} = 1.5 \quad \text{(NTC2008 Table 2.6.I)}
\]
\[
\gamma_{Q,1,\text{inf}} = 0.0 \quad \text{(NTC2008 Table 2.6.I)}
\]
\[
\gamma_{Q,I,\text{sup}} = 1.5 \quad \text{(NTC2008 Table 2.6.I)}
\]
\[
\gamma_{Q,I,\text{inf}} = 0.0 \quad \text{(NTC2008 Table 2.6.I)}
\]
\[
\psi_{0,i} = 0.7 \text{ (live load, assumed not to be storage)} \quad \text{(Table 2.5.I)}
\]
\[
\psi_{0,i} = 0.6 \text{ (wind load)} \quad \text{(Table 2.5.I)}
\]
\[
\psi_{0,i} = 0.5 \text{ (snow load, assumed } H \leq 1,000 \text{ m)} \quad \text{(Table 2.5.I)}
\]
\[
\psi_{2,i} = 0.3 \text{ (live, assumed office/residential space)} \quad \text{(Table 2.5.I)}
\]
\[
\psi_{2,i} = 0 \text{ (snow, assumed } H \leq 1,000 \text{ m)} \quad \text{(Table 2.5.I)}
\]

If roof live load is treated separately or other types of loads are present, other appropriate load combinations should be used.

14.3 Limits on Material Strength

The concrete compressive strength, \( f_{ck} \), should not be greater than 90 MPa (NTC2008 Tab. 4.1.I). The reinforcement material should be B450C or B450A (NTC2008 §11.3.2).

**NTC Table 11.3.Ia:**

<table>
<thead>
<tr>

</tr>
</tbody>
</table>
14.4 Partial Safety Factors

The design strengths for concrete and steel are obtained by dividing the characteristic strengths of the materials by the partial safety factors, $\gamma_s$ and $\gamma_c$ as shown here.

$$f_{cd} = \alpha_{cc} f_{ck} / \gamma_c$$  \hspace{1cm} (NTC Eq. 4.1.4)

$$f_{yd} = f_{yk} / \gamma_s$$  \hspace{1cm} (NTC Eq. 4.1.6)

$$f_{ywd} = f_{ywk} / \gamma_s$$  \hspace{1cm} (NTC Eq. 4.1.6)

$\alpha_{cc}$ is the coefficient taking account of long term effects on the compressive strength. $\alpha_{cc}$ is taken as 0.85 (NTC2008 4.1.2.1.1.1) by default and can be overwritten by the user.
Chapter 14 - Design for Italian NTC 2008

The partial safety factors for the materials and the design strengths of concrete and reinforcement are given in the text that follows (NTC2008 4.1.2.1.1.1-3):

Partial safety factor for reinforcement, $\gamma_s = 1.15$

Partial safety factor for concrete, $\gamma_c = 1.5$

These values can be overwritten; however, caution is advised.

14.5 Slab Design

ETABS slab design procedure involves defining sets of strips in two mutually perpendicular directions. The locations of the strips are usually governed by the locations of the slab supports. The axial force, moments and shears for a particular strip are recovered from the analysis (on the basis of the Wood-Armer technique), and a flexural design is carried out based on the ultimate strength design method.

The slab design procedure involves the following steps:

- Design flexural reinforcement
- Design shear reinforcement
- Punching check

14.5.1 Design Flexural Reinforcement

For slabs, ETABS uses either design strips or the finite element based design to calculate the slab flexural reinforcement in accordance with the selected design code. For simplicity, only strip-by-strip design is documented in the proceeding sections.

The design of the slab reinforcement for a particular strip is carried out at specific locations along the length of the strip. These locations correspond to the element boundaries. Controlling reinforcement is computed on either side of those element boundaries. The slab flexural design procedure for each load combination involves the following:

- Determine factored axial loads and moments for each slab strip.
Design flexural reinforcement for the strip.

These two steps, described in the text that follows, are repeated for every load combination. The maximum reinforcement calculated for the top and bottom of the slab within each design strip, along with the corresponding controlling load combination, is obtained and reported.

14.5.1.1 Determine Factored Moments

In the design of flexural reinforcement of concrete slab, the factored moments for each load combination at a particular design strip are obtained by factoring the corresponding moments for different load cases, with the corresponding load factors.

The slab is then designed for the maximum positive and maximum negative factored moments obtained from all of the load combinations. Calculation of bottom reinforcement is based on positive design strip moments. In such cases, the slab may be designed as a rectangular or flanged slab section. Calculation of top reinforcement is based on negative design strip moments. In such cases, the slab may be designed as a rectangular or inverted flanged slab section.

14.5.1.2 Determine Required Flexural Reinforcement

In the flexural reinforcement design process, the program calculates both the tension and compression reinforcement. Compression reinforcement is added when the applied design moment exceeds the maximum moment capacity of a singly reinforced section. The user can avoid the need for compression reinforcement by increasing the effective depth, the width, or the grade of concrete.

The design procedure is based on a simplified rectangular stress block, as shown in Figure 14-1 (NTC Fig. 4.1.3). When the applied moment exceeds the moment capacity, the area of compression reinforcement is calculated on the assumption that the additional moment will be carried by compression and additional tension reinforcement.

The design procedure used by the program for both rectangular and flanged sections (T-shaped section) is summarized in the following subsections. For reinforced concrete design where design ultimate axial compression load does not
Chapter 14 - Design for Italian NTC 2008

exceed \(0.1f_{cd}A_g\), axial force is ignored; hence, all slabs are designed for major direction flexure, shear, and torsion only. Axial compression greater than \(0.1f_{cd}A_g\) and axial tensions are always included in flexural and shear design.

In designing for a factored negative or positive moment, \(M_{Ed}\) (i.e., designing top or bottom steel), the effective strength and depth of the compression block are given by \(\alpha_{cc,f_{cd}}\) and \(\beta x\) (see Figure 14-1) respectively, where:

\[
\beta = 0.8 \quad \text{(NTC § 4.1.2.1.2.2)}
\]

\[
\alpha_{cc} = 0.85 \quad \text{(NTC § 4.1.2.1.2.2)}
\]

\[
f_{cd} = \alpha_{cc} \frac{f_{ck}}{\gamma_c} \quad \text{if } f_{ck} \leq 50N / mm^2
\]

\[
\alpha_{cc} = 0.85
\]

\[
\gamma_c = 1.5
\]

if \(f_{ck} > 50N / mm^2\) NTC 2008 refer to Eurocode 2:
\[ f_{cd} = \alpha_{cw} \frac{f_{ck}}{\gamma_c} \]

\[ \eta = 1.0 - (f_{ck} - 50)/200 \text{ for } 50 < f_{ck} \leq 90 \text{ MPa} \]  
EC2 Eq. 3.22

For the design of the slab, a ductility criterion, suggested in Eurocode 2 § 5.5, is followed.

The limiting value of the ratio of the neutral axis depth at the ultimate limit state to the effective depth, \((x/d)_{\text{lim}}\), is expressed as a function of the ratio of the redistributed moment to the moment before redistribution, \(\delta\), as follows:

\[ (x/d)_{\text{lim}} = (\delta - k_1)/k_2 \text{ for } f_{ck} \leq 50 \text{ MPa} \]  
EC2 Eq. 5.10a

\[ (x/d)_{\text{lim}} = (\delta - k_3)/k_4 \text{ for } f_{ck} > 50 \text{ MPa} \]  
EC2 Eq. 5.10b

No redistribution is assumed, such that \(\delta\) is assumed to be 1. The four factors, \(k_1\), \(k_2\), \(k_3\), and \(k_4\) are defined as:

\[ k_1 = 0.44 \]  
EC2 5.5(4)

\[ k_2 = 1.25(0.6 + 0.0014/\varepsilon_{cu}) \]  
EC2 5.5(4)

\[ k_3 = 0.54 \]  
EC2 5.5(4)

\[ k_4 = 1.25(0.6 + 0.0014/\varepsilon_{cu}) \]  
EC2 5.5(4)

where the ultimate strain, \(\varepsilon_{cu,2}\), is determined from EC2 Table 3.1 as:

\[ \varepsilon_{cu,2} = 0.0035 \text{ for } f_{ck} < 50 \text{ MPa} \]  
NTC § 4.1.2.1.2.2

\[ \varepsilon_{cu,2} = 2.6 + 35\left[\frac{(90 - f_{ck})}{100}\right]^4 \text{ for } f_{ck} \geq 50 \text{ MPa} \]  
NTC § 4.1.2.1.2.2

### 14.5.1.2.1 Uniform Thickness Slab Flexural Reinforcement

For uniform thickness slab, the normalized moment, \(m\), and the normalized section capacity as a singly reinforced section, \(m_{\text{lim}}\), are determined as:

\[ m = \frac{M}{bd^2 f_{cd}} \]
The reinforcing steel area is determined based on whether $m$ is greater than, less than, or equal to $m_{\text{lim}}$.

- If $m \leq m_{\text{lim}}$, a singly reinforced slab will be adequate. Calculate the normalized steel ratio, $\omega$, and the required area of tension reinforcement, $A_s$, as:

$$\omega = 1 - \sqrt{1 - 2m}$$

$$A_s = \omega \left[ \frac{f_{cd}bd}{f_{yd}} \right]$$

This area of reinforcing steel is to be placed at the bottom if $M_{Ed}$ is positive, or at the top if $M_{Ed}$ is negative.

- If $m > m_{\text{lim}}$, compression reinforcement is required. Calculate the normalized steel ratios, $\omega'$, $\omega_{\text{lim}}$, and $\omega$, as:

$$\omega_{\text{lim}} = \beta \left( \frac{x}{d} \right)_{\text{lim}} = 1 - \sqrt{1 - 2m_{\text{lim}}}$$

$$\omega' = \frac{m - m_{\text{lim}}}{1 - d'/d}$$

$$\omega = \omega_{\text{lim}} + \omega'$$

where $d'$ is the depth to the compression steel, measured from the concrete compression face.

Calculate the required area of compression and tension reinforcement, $A_{s'}$ and $A_s$, as:

$$A_{s'} = \omega' \left[ \frac{f_{cd}bd}{f_{yd}'} \right]$$
\[ A_s = \omega \left[ \frac{f_{yd} b d}{f_{yd}} \right] \]

where \( f_{s}' \), the stress in the compression steel, is calculated as:

\[ f_{s}' = E_s \varepsilon_c \left[ 1 - \frac{d'}{x_{lim}} \right] \leq f_{yd} \]

\( A_s \) is to be placed at the bottom and \( A_{s}' \) is to be placed at the top if \( M_{Ed} \) is positive, and \( A_{s}' \) is to be placed at the bottom and \( A_s \) is to be placed at the top if \( M_{Ed} \) is negative.

### 14.5.1.2.2 Nonuniform Thickness Slab Flexural Reinforcement

In designing a T-shaped slab section, a simplified stress block, as shown in Figure 14-2, as assumed if the flange is in compression, i.e., if the moment is positive. If the moment is negative, the flange is in tension, and therefore ignored. In that case, a simplified stress block, similar to that shown in Figure 14-2, is assumed on the compression side.

#### 14.5.1.2.2.1 Flanged Slab Section Under Negative Moment

In designing for a factored negative moment, \( M_{Ed} \) (i.e., designing top steel), the calculation of the reinforcing steel area is exactly the same as described for a uniform thickness slab, i.e., no specific flanged data is used.

#### 14.5.1.2.2.2 Flanged Slab Section Under Positive Moment

In designing for a factored positive moment, \( M_{Ed} \), the program analyzes the section by considering the depth of the stress block. If the depth of the stress block is less than or equal to the flange thickness, the section is designed as a uniform thickness with a width \( b_f \). If the stress block extends into the web, additional calculation is required.

For flanged-shaped section, the normalized moment, \( m \), and the normalized section capacity as a singly reinforced section, \( m_{lim} \), are calculated as:
$$m = \frac{M}{b_fd^2 f_{cd}}$$

$$m_{\text{lim}} = \beta \left( \frac{x}{d} \right)_{\text{lim}} \left[ 1 - \frac{\beta}{2} \left( \frac{x}{d} \right)_{\text{lim}} \right]$$

Calculate the normalized steel ratios $\omega_{\text{lim}}$ and $\omega$, as:

$$\omega_{\text{lim}} = \beta \left( \frac{x}{d} \right)_{\text{lim}}$$

$$\omega = 1 - \sqrt{1 - 2m}$$

Calculate the maximum depth of the concrete compression block, $x_{\text{max}}$, and the effective depth of the compression block, $x$, as:

$$x_{\text{max}} = \omega_{\text{lim}} d$$

$$x = \omega d$$

The reinforcing steel area is determined based on whether $m$ is greater than, less than, or equal to $m_{\text{lim}}$.

- If $x \leq h_f$, the subsequent calculations for $A_s$ are exactly the same as previously defined for uniform thickness slab design. However, in this case, the width of the slab is taken as $b_f$, as shown in Figure 14-2. Compression reinforcement is required if $m > m_{\text{lim}}$.

- If $x > h_f$, the calculation for $A_s$ has two parts. The first part is for balancing the compressive force from the flange, and the second part is for balancing the compressive force from the web, as shown in Figure 14-2.

- The required reinforcing steel area, $A_{s2}$, and corresponding resistive moment, $M_2$, for equilibrating compression in the flange outstands are calculated as:

$$A_{s2} = \frac{(b_f - b_n)h_f f_{cd}}{f_{yd}}$$
Now calculate the required reinforcing steel area $A_{sl}$ for the rectangular section of width $b_w$ to resist the remaining moment $M_1 = M_{Ed} - M_2$. The normalized moment, $m_1$, is calculated as:

$$m_1 = \frac{M_1}{b_w d f_{cd}}$$

The reinforcing steel area is determined based on whether $m_1$ is greater than, less than, or equal to $m_{lim}$.

- If $m_1 \leq m_{lim}$, a singly reinforced section will be adequate. Calculate the normalized steel ratio, $\omega_1$, and the required area of tension reinforcement, $A_{st}$, as:

$$\omega_1 = 1 - \sqrt{1 - 2m}$$

$$A_{sl} = \omega_1 \left[ \frac{f_{cd}bd}{f_{yd}} \right]$$
If $m_1 > m_{\text{lim}}$, compression reinforcement is required. Calculate the normalized steel ratios, $\omega'$, $\omega_{\text{lim}}$, and $\omega_1$ as:

$$\omega_{\text{lim}} = \beta \left( \frac{x'}{d} \right)_{\text{lim}}$$

$$\omega' = \frac{m - m_{\text{lim}}}{1 - d'/d}$$

$$\omega_1 = \omega_{\text{lim}} + \omega'$$

where $d'$ is the depth to the compression steel, measured from the concrete compression face.

Calculate the required area of compression and tension reinforcement, $A_{s'}$ and $A_s$, as:

$$A_{s'} = \omega' \left[ \frac{f_{s'd}}{f_s'} \right]$$

$$A_{s1} = \omega_1 \left[ \frac{f_{s'd}}{f_{yd}} \right]$$

where $f_s'$, the stress in the compression steel, is calculated as:

$$f_s' = E_s \varepsilon_c \left[ 1 - \frac{d'}{x_{\text{lim}}} \right] \leq f_{yd}$$

The total tensile reinforcement is $A_s = A_{s1} + A_{s2}$, and the total compression reinforcement is $A_{s'}$. $A_s$ is to be placed at the bottom and $A_{s'}$ is to be placed at the top of the section.

### 14.5.1.3 Minimum and Maximum Tensile Reinforcement

The minimum flexural tension reinforcement required for each direction of a slab is given by the following limits:
ETABS Reinforced Concrete Design

\[ A_{s,\min} = 0.26 \frac{f_{cm}}{f_{yk}} bd \]  
\[ A_{s,\min} = 0.0013bd \]  

(NTC Eq. 4.1.43)

where \( f_{cm} \) is the mean value of axial tensile strength of the concrete and is computed as:

\[ f_{cm} = 0.30 f_{ck}^{(2/3)} \text{ for } f_{ck} \leq 50 \text{ MPa} \]  
\[ f_{cm} = 2.12 \ln \left(1 + \frac{f_{cm}}{10}\right) \text{ for } f_{ck} > 50 \text{ MPa} \]  
\[ f_{cm} = f_{ck} + 8 \text{ MPa} \]  

(NTC Eq. 11.2.2)

(NTC Eq. 11.2.3a)

(NTC Eq. 11.2.3b)

The minimum flexural tension reinforcement required for control of cracking should be investigated independently by the user.

An upper limit on the tension reinforcement and compression reinforcement has been imposed to be 0.04 times the gross cross-sectional area (NTC § 4.1.6.1.1).

14.5.2 Design Slab Shear Reinforcement

The shear reinforcement is designed for each load combination at each station along the design strip. In designing the shear reinforcement for a particular strip, for a particular load combination, at a particular station due to the slab major shear, the following steps are involved.

- Determine the design forces acting on the section, \( N_{Ed} \) and \( V_{Ed} \). Note that \( N_{Ed} \) is needed for the calculation of \( V_{Rcd} \).
- Determine the maximum design shear force that can be carried without crushing of the notional concrete compressive struts, \( V_{Rcd} \).
- Determine the required shear reinforcement as area per unit length, \( A_{sw} / s \).

The following three sections describe in detail the algorithms associated with this process.
14.5.2.1 Determine Design Shear Force

In the design of the slab shear reinforcement, the shear forces and moments for a particular design load combination at a particular strip are obtained by factoring the associated shear forces and moments with the corresponding design load combination factors.

14.5.2.2 Determine Concrete Shear Capacity

The shear force carried by the concrete, $V_{rd,c}$, is calculated as:

$$V_{rd,c} = \left[ C_{rd,c} k \left( 100 \rho_t f_{ck} \right)^{1/3} + k_1 \sigma_{cp} \right] b \cdot d$$

with a minimum of:

$$V_{rd,c} = \left( v_{min} + k_1 \sigma_{cp} \right) b \cdot d$$

where

- $f_{ck}$ is in MPa
- $k = 1 + \sqrt{\frac{200}{d}} \leq 2.0$ with $d$ in mm

$$\rho_t = \text{tension reinforcement ratio} = \frac{A_{st}}{b \cdot d} \leq 0.02$$

$$A_{st} = \text{area of tension reinforcement}$$

$$\sigma_{cp} = \frac{N_{Ed}}{A_c} < 0.2 f_{cd} \text{ MPa}$$

The value of $C_{rd,c}$, $v_{min}$ and $k_1$ for use in a country may be found in its National Annex. The program default values for $C_{rd,c}$, $v_{min}$ and $k_1$ are given as follows (EC2 6.2.2(1)):

- $C_{rd,c} = 0.18/\gamma_c$  

  \hspace{1cm} (EC2 6.2.2(1))

- $v_{min} = 0.035 k^{3/2} f_{ck}^{1/2}$  

  \hspace{1cm} (EC2 6.2.2(1))

- $k_1 = 0.15$  

  \hspace{1cm} (EC2 6.2.2(1))
For light-weight concrete:

\[ C_{Rd,c} = \frac{0.18}{\gamma_c} \quad \text{(EC2 11.6.1(1))} \]

\[ v_{\text{min}} = 0.03 \, k^{3/2} f_{ck}^{1/2} \quad \text{(EC2 11.6.1(1))} \]

\[ k_I = 0.15. \quad \text{(EC2 11.6.1(1))} \]

### 14.5.2.3 Determine Maximum Design Shear Force

To prevent crushing of the concrete compression struts, the design shear force \( V_{Ed} \) is limited by the maximum sustainable design shear force, \( V_{Rcd} \). If the design shear force exceeds this limit, a failure condition occurs. The maximum sustainable shear force is defined as:

\[
V_{Rcd} = 0.9 \cdot d \cdot b_w \cdot \alpha_c f'_{cd} \cdot \frac{\cot \alpha + \cot \theta}{1 + \cot^2 \theta} \quad \text{(NTC Eq. 4.1.19)}
\]

\[ \alpha_c = 1 \text{ for members not subjected to axial compression} \]

\[
= 1 + \frac{\sigma_{cp}}{f_{cd}} \text{ for } 0 \leq \sigma_{cp} \leq 0.25 f_{cd}
\]

\[
= 1.25 \text{ for } 0.25 f_{cd} \leq \sigma_{cp} \leq 0.5 f_{cd}
\]

\[
= 2.5 \left( 1 + \frac{\sigma_{cp}}{f_{cd}} \right) \text{ for } 0.5 f_{cd} \leq \sigma_{cp} \leq f_{cd}
\]

\[ f'_{cd} = 0.5 f_{cd} \]

\[ \alpha \quad \text{angle between the shear reinforcement and the column axis. In the case of vertical stirrups } \alpha = 90 \text{ degrees} \]

\[ \theta \quad \text{angle between the concrete compression struts and the column axis. NTC 2008 allows } \theta \text{ to be taken between 21.8 and 45 degrees.} \]

### 14.5.2.4 Determine Required Shear Reinforcement

If \( V_{Ed} \) is less than \( V_{Rcd} \), the required shear reinforcement in the form of stirrups or ties per unit spacing, \( A_{sw}/s \), is calculated as:
\[
\frac{A_{sw}}{s} = \frac{V_{Ed}}{0.9d \cdot f_{yw,tul}} \cdot \frac{1}{(\cot \alpha + \cot \theta) \sin \alpha}
\]  
(NTC Eq. 4.1.18)

with \( \alpha = 90 \) degrees and \( \theta \) given in the previous section.

The maximum of all of the calculated \( A_{sw}/s \) values, obtained from each design load combination, is reported for the major direction of the slab, along with the controlling combination name.

The calculated shear reinforcement must be greater than the minimum reinforcement:

\[
A_{sw, \text{min}} = 1.5 \cdot b
\]

with \( b \) in millimeters and \( A_{sw, \text{min}} \) in mm\(^2/mm\).

The slab shear reinforcement requirements reported by the program are based purely on shear strength consideration. Any minimum stirrup requirements to satisfy spacing considerations or transverse reinforcement volumetric considerations must be investigated independently by the user.

**14.5.3 Check for Punching Shear**

The algorithm for checking punching shear is detailed in the section entitled “Slab Punching Shear Check” in the Chapter 1. Only the code-specific items are described in the following sections.

NTC2008 for the punching shear check refers to Eurocode2-2004.

**14.5.3.1 Critical Section for Punching Shear**

The punching shear is checked at the face of the column (EC2 6.4.1(4)) and at a critical section at a distance of 2.0d from the face of the support (EC2 6.4.2(1)). The perimeter of the critical section should be constructed such that its length is minimized. Figure 6-3 shows the auto punching perimeters considered by ETABS for the various column shapes. The column location (i.e., interior, edge, corner) and the punching perimeter may be overwritten using the Punching Check Overwrites.
Determination of Concrete Capacity

The concrete punching shear stress capacity is taken as:

\[ V_{rd,c} = \left[ C_{rd,c} k \left( 100 \rho_y f_{yk} \right)^{1/3} + k_1 \sigma_{cp} \right] \]

with a minimum of:

\[ V_{rd,c} = \left( v_{min} + k_1 \sigma_{cp} \right) \]

where \( f_{ck} \) is in MPa and

\[ k = 1 + \sqrt{\frac{200}{d}} \leq 2.0 \text{ with } d \text{ in mm} \]

\[ \rho_1 = \sqrt{\rho_{1x} \rho_{1y}} \leq 0.02 \]

where \( \rho_{1x} \) and \( \rho_{1y} \) are the reinforcement ratios in the \( x \) and \( y \) directions respectively, conservatively taken as zeros, and

\[ \sigma_{cp} = (\sigma_{cx} + \sigma_{cy})/2 \]
where $\sigma_{cx}$ and $\sigma_{cy}$ are the normal concrete stresses in the critical section in the $x$ and $y$ directions respectively, conservatively taken as zeros.

$$
C_{bd,c} = 0.18/\gamma_c 
$$

(EC2 6.4.4(1))

$$
\nu_{\min} = 0.035k^{3/2}f_{ck}^{1/2} 
$$

(EC2 6.4.4(1))

$$
k_1 = 0.15 
$$

(EC2 6.4.4(1))

### 14.5.3.3 Determine Maximum Shear Stress

Given the punching shear force and the fractions of moments transferred by eccentricity of shear, the nominal design shear stress, $\nu_{Ed}$, is calculated as:

$$
\nu_{Ed} = \frac{V_{Ed}}{ud} \left[ 1 + k \frac{M_{Ed,z}u_1}{V_{Ed}W_{1,2}} + k \frac{M_{Ed,z}u_1}{V_{Ed}W_{1,3}} \right], \text{ where} 
$$

(EC2 6.4.4(2))

$k$ is the function of the aspect ratio of the loaded area in Table 14.1 of EN 1992-1-1

$u_1$ is the effective perimeter of the critical section

$d$ is the mean effective depth of the slab

$M_{Ed}$ is the design moment transmitted from the slab to the column at the connection along bending axis 2 and 3

$V_{Ed}$ is the total punching shear force

$W_1$ accounts for the distribution of shear based on the control perimeter along bending axis 2 and 3.

### 14.5.3.4 Determine Capacity Ratio

The ratio of the maximum shear stress and the concrete punching shear stress capacity is reported as the punching shear capacity ratio by ETABS. If this ratio exceeds 1.0, punching shear reinforcement is designed as described in the following section.
14.5.4 Design Punching Shear Reinforcement

The use of shear studs as shear reinforcement in slabs is permitted, provided that the effective depth of the slab is greater than or equal to 200 mm.

The algorithm for designing the required punching shear reinforcement is used when the punching shear capacity ratio exceeds unity. The Critical Section for Punching Shear and Transfer of Unbalanced Moment as described in the earlier sections remain unchanged. The design of punching shear reinforcement is performed as described in the subsections that follow.

14.5.4.1 Determine Concrete Shear Capacity

The concrete punching shear stress capacity of a section with punching shear reinforcement is as previously determined for the punching check.

14.5.4.2 Determine Required Shear Reinforcement

The shear is limited to a maximum of $V_{Rcd}$ calculated in the same manner as explained previously for slabs.

Given $v_{Ed}$, $v_{Rd,c}$, and $v_{Rcd}$, the required shear reinforcement is calculated as follows (EC2 6.4.5).

- If $v_{R,dc} < v_{Ed} \leq v_{Rcd}$, the concrete section should be increased in size. (EC2 6.2.3(3))
- If $v_{Ed} > v_{Rcd}$, a failure condition is declared. (EC2 6.2.3(3))
- If $v_{Ed}$ exceeds the maximum permitted value of $V_{Rcd}$, the concrete section should be increased in size.

14.5.4.3 Determine Reinforcement Arrangement

Punching shear reinforcement in the vicinity of rectangular columns should be arranged on peripheral lines, i.e., lines running parallel to and at constant distances from the sides of the column. Figure 6-4 shows a typical arrangement of shear reinforcement in the vicinity of a rectangular interior, edge, and corner column.
Chapter 14 - Design for Italian NTC 2008

Figure 6-4 Typical arrangement of shear studs and critical sections outside shear-reinforced zone

The distance between the column face and the first line of shear reinforcement shall not exceed $2d$. The spacing between adjacent shear reinforcement in the first line (perimeter) of shear reinforcement shall not exceed $1.5d$ measured in a direction parallel to the column face (EC2 9.4.3(1)).

Punching shear reinforcement is most effective near column corners where there are concentrations of shear stress. Therefore, the minimum number of lines of shear reinforcement is 4, 6, and 8, for corner, edge, and interior columns respectively.

14.5.4.4 Determine Reinforcement Diameter, Height, and Spacing

The punching shear reinforcement is most effective when the anchorage is close to the top and bottom surfaces of the slab. The cover of anchors should not be less than the minimum cover specified in EC2 4.4.1 plus half of the diameter of the flexural reinforcement.

Punching shear reinforcement in the form of shear studs is generally available in 10-, 12-, 14-, 16-, and 20-millimeter diameters.

When specifying shear studs, the distance, $s_o$, between the column face and the first peripheral line of shear studs should not be smaller than $0.3d$. The spacing
between adjacent shear studs, $g$, at the first peripheral line of studs shall not exceed $1.5d$ and should not exceed $2d$ at additional perimeters. The limits of $s_o$ and the spacing, $s$, between the peripheral lines are specified as:

\[
0.3d \leq s_o \leq 2d \quad \text{(EC2 9.4.3(1))}
\]

\[
s \leq 0.75d \quad \text{(EC2 9.4.3(1))}
\]

\[
g \leq 1.5d \text{ (first perimeter)} \quad \text{(EC2 9.4.3(1))}
\]

\[
g \leq 2d \text{ (additional perimeters)} \quad \text{(EC2 9.4.3(1))}
\]
This chapter describes in detail the various aspects of the concrete design procedure that is used by ETABS when the New Zealand code NZS 3101-06 [NZS 06] is selected. Various notations used in this chapter are listed in Table 15-1. For referencing to the pertinent sections of the New Zealand code in this chapter, a prefix “NZS” followed by the section number is used.

The design is based on user-specified load combinations. The program provides a set of default load combinations that should satisfy the requirements for the design of most building type structures.

English as well as SI and MKS metric units can be used for input. The code is based on Newton-millimeter-second units. For simplicity, all equations and descriptions presented in this chapter correspond to Newton-millimeter-second units unless otherwise noted.

15.2 Design Load Combinations

The design load combinations are the various combinations of the load cases for which the structure needs to be designed. For NZS 3101-06, if a structure is subjected to dead (D), live (L), pattern live (PL), snow (S), wind (W), and earthquake (E) loads, and considering that wind and earthquake forces are reversible, the following load combinations may need to be considered (AS/NZS 1170.0, 4.2.2):

1.35D \hspace{2cm} (AS/NZS 1170.0, 4.2.2(a))
1.2D + 1.5L \hspace{1cm} (AS/NZS 1170.0, 4.2.2(b))
1.2D + 1.5(0.75 PL) \hspace{0.5cm} (AS/NZS 1170.0, 4.2.2(b))
1.2D + 0.4L + 1.0S \hspace{0.5cm} (AS/NZS 1170.0, 4.2.2(g))
1.2D ± 1.0W \hspace{1.5cm} (AS/NZS 1170.0, 4.2.2(d))
0.9D ± 1.0W \hspace{1.5cm} (AS/NZS 1170.0, 4.2.2(e))
1.2D + 0.4L ± 1.0W \hspace{0.5cm} (AS/NZS 1170.0, 4.2.2(d))
1.0D ± 1.0E \hspace{2cm} (AS/NZS 1170.0, 4.2.2(f))
1.0D + 0.4L ± 1.0E \hspace{0.5cm} (AS/NZS 1170.0, 4.2.2(f))
Note that the 0.4 factor on the live load in three of the combinations is not valid for live load representing storage areas. These are also the default design load combinations in ETABS whenever the NZS 3101-06 code is used. If roof live load is treated separately or if other types of loads are present, other appropriate load combinations should be used.

15.3 Limits on Material Strength

The upper and lower limits of $f'_c$ shall be as follows:

$$25 \leq f'_c \leq 100 \text{ MPa} \quad \text{(NZS 5.2.1)}$$

The lower characteristic yield strength of longitudinal reinforcement, $f_y$, should be equal to or less than 500 MPa for all frames (NZS 5.3.3). The lower characteristic yield strength of transverse (stirrup) reinforcement, $f_{yt}$, should not be greater than 500 MPa for shear or 800 MPa for confinement (NZS 5.3.3).

The code allows use of $f'_c$ and $f_y$ beyond the given limits, provided special study is conducted (NZS 5.2.1).

ETABS enforces the upper material strength limits for flexure and shear design of slabs. The input material strengths are taken as the upper limits if they are defined in the material properties as being greater than the limits. The user is responsible for ensuring that the minimum strength is satisfied.

15.4 Strength Reduction Factors

The strength reduction factors, $\phi$, are applied to the specified strength to obtain the design strength provided by a member. The $\phi$ factors for flexure, shear, and torsion are as follows:

$$\phi_b = 0.85 \text{ for flexure} \quad \text{(NZS 2.3.2.2)}$$

$$\phi_s = 0.75 \text{ for shear and torsion} \quad \text{(NZS 2.3.2.2)}$$

These values can be overwritten; however, caution is advised.
ETABS Reinforced Concrete Design

15.5  Slab Design

ETABS slab design procedure involves defining sets of strips in two mutually perpendicular directions. The locations of the strips are usually governed by the locations of the slab supports. The axial force, moments and shears for a particular strip are recovered from the analysis (on the basis of the Wood-Armer technique), and a flexural design is carried out based on the ultimate strength design method.

The slab design procedure involves the following steps:

Design flexural reinforcement
Design shear reinforcement
Punching check

15.5.1 Design Flexural Reinforcement

For slabs, ETABS uses either design strips or the finite element based design to calculate the slab flexural reinforcement in accordance with the selected design code. For simplicity, only strip-by-strip design is document in the proceeding sections.

The design of the slab reinforcement for a particular strip is carried out at specific locations along the length of the strip. These locations correspond to the element boundaries. Controlling reinforcement is computed on either side of those element boundaries. The slab flexural design procedure for each load combination involves the following:

Determine factored axial loads and moments for each slab strip.

Design flexural reinforcement for the strip.

These two steps, described in the text that follows, are repeated for every load combination. The maximum reinforcement calculated for the top and bottom of the slab within each design strip, along with the corresponding controlling load combination, is obtained and reported.
15.5.1.1 Determine Factored Moments

In the design of flexural reinforcement of concrete slab, the factored moments for each load combination at a particular design strip are obtained by factoring the corresponding moments for different load cases, with the corresponding load factors.

The slab is then designed for the maximum positive and maximum negative factored moments obtained from all of the load combinations. Calculation of bottom reinforcement is based on positive design strip moments. In such cases, the slab may be designed as a rectangular or flanged slab section. Calculation of top reinforcement is based on negative design strip moments. In such cases, the slab may be designed as a rectangular or inverted flanged slab section.

15.5.3.2 Determine Required Flexural Reinforcement

In the flexural reinforcement design process, the program calculates both the tension and compression reinforcement. Compression reinforcement is added when the applied design moment exceeds the maximum moment capacity of a singly reinforced section. The user has the option of avoiding the compression reinforcement by increasing the effective depth, the width, or the strength of the concrete.

The design procedure is based on the simplified rectangular stress block shown in Figure 15-1 (NZS 7.4.2.7). Furthermore, it is assumed that the compression carried by the concrete is 0.75 times that which can be carried at the balanced condition (NZS 9.3.8.1). When the applied moment exceeds the moment capacity at the balanced condition, the area of compression reinforcement is calculated assuming that the additional moment will be carried by compression reinforcement and additional tension reinforcement.
The design procedure used by ETABS, for both rectangular and flanged sections (L- and T-shaped sections), is summarized in the text that follows. For reinforced concrete design where design ultimate axial compression load does not exceed \(0.1 f'_c A_g\), axial force is ignored; hence, all slabs are designed for major direction flexure, shear, and torsion only. Axial compression greater than \(0.1 f'_c A_g\) and axial tensions are always included in flexural and shear design.

### 15.5.1.2.1 Design of uniform thickness slab

In designing for a factored negative or positive \(M^*\) (i.e., designing top or bottom reinforcement), the depth of the compression block is given by \(a\) (see Figure 15-1), where,

\[
a = d - \sqrt{d^2 - \frac{2|M^*|}{\alpha f'_c \phi_b b}}
\]

(NZS 7.4.2)

where the default value of \(\phi_b\) is 0.85 (NZS 2.3.2.2) in the preceding and following equations. The factor \(\alpha_t\) is calculated as follows (NZS 7.4.2.7):

---

**Figure 15-1 Uniform Thickness Slab Design**

![Diagram of uniform thickness slab design](image-url)
\[ \alpha_t = 0.85 \text{ for } f'_c \leq 55 \text{MPa} \]
\[ \alpha_t = 0.85 - 0.004(f'_c - 55) \text{ for } f'_c \geq 55 \text{MPa}, \quad 0.75 \leq \alpha_t \leq 0.85 \]

The value \( \beta_t \) and \( c_b \) are calculated as follows:
\[ \beta_t = 0.85 \text{ for } f'_c \leq 30, \quad (\text{NZS 7.4.2.7}) \]
\[ \beta_t = 0.85 - 0.008(f'_c - 30), \quad 0.65 \leq \beta_t \leq 0.85 \quad (\text{NZS 7.4.2.7}) \]
\[ c_b = \frac{\varepsilon_c}{\varepsilon_c + f'_y / E_s} d \quad (\text{NZS 7.4.2.8}) \]

The maximum allowed depth of the rectangular compression block, \( a_{\text{max}} \), is given by:
\[ a_{\text{max}} = 0.75 \beta_t c_b \quad (\text{NZS 7.4.2.7, 9.3.8.1}) \]

If \( a \leq a_{\text{max}} \) (NZS 9.3.8.1), the area of tension reinforcement is given by:
\[ A_t = \frac{M^*}{\phi_b f'_y \left( d - \frac{a}{2} \right)} \]

The reinforcement is to be placed at the bottom if \( M^* \) is positive, or at the top if \( M^* \) is negative.

- If \( a > a_{\text{max}} \) (NZS 9.3.8.1), compression reinforcement is required (NZS 7.4.2.9) and is calculated as follows:

The compressive force developed in the concrete alone is given by:
\[ C = \alpha_t f'_c ba_{\text{max}} \quad (\text{NZS 7.4.2.7}) \]

and the moment resisted by concrete compression and tension reinforcement is:
\[ M'_c = C \left( d - \frac{a_{\text{max}}}{2} \right) \phi_b \]
Therefore the moment required to be resisted by compression reinforcement and tension reinforcement is:

\[ M' = M' - M'_c \]

The required compression reinforcement is given by:

\[ A'_s = \frac{M'_s}{(f'_s - \alpha_s f'_c)(d - d') \phi_b} \text{, where} \]

\[ f'_s = \epsilon_{c, \text{max}} E_s \left[ \frac{c - d'}{c} \right] \leq f_y \quad \text{(NZS 7.4.2.2, 7.4.2.4)} \]

The required tension reinforcement for balancing the compression in the concrete is:

\[ A_{s1} = \frac{M'_c}{f_y \left( d - \frac{a_{\text{max}}}{2} \right) \phi_b} \]

and the tension reinforcement for balancing the compression reinforcement is given by:

\[ A_{s2} = \frac{M'_s}{f_y (d - d') \phi_b} \]

Therefore, the total tension reinforcement, \( A_s = A_{s1} + A_{s2} \), and the total compression reinforcement is \( A'_s \). \( A_s \) is to be placed at the bottom and \( A'_s \) is to be placed at the top if \( M' \) is positive, and vice versa if \( M' \) is negative.

15.5.1.2.2 Design of nonuniform thickness slab

15.5.1.2.2.1 Flanged Slab Section Under Negative Moment

In designing for a factored negative moment, \( M' \) (i.e., designing top reinforcement), the calculation of the reinforcement area is exactly the same as described previously, i.e., no flanged data is used.
15.5.1.2.2.2 Flanged Slab Section Under Positive Moment

If \( M^* > 0 \), the depth of the compression block is given by:

\[
a = d - \sqrt{d^2 - \frac{2M^*}{\alpha_1 f'c_b b_f}} \quad \text{(NZS 7.4.2)}
\]

The maximum allowable depth of the rectangular compression block, \( a_{\text{max}} \), is given by:

\[
a_{\text{max}} = 0.75 \beta_1 c_b \quad \text{(NZS 7.4.2.7, 9.3.8.1)}
\]

If \( a \leq h_f \), the subsequent calculations for \( A_s \) are exactly the same as previously defined for the uniform thickness slab design. However, in this case the width of the slab is taken as \( b_f \). Compression reinforcement is required when \( a > a_{\text{max}} \).

If \( a > h_f \), calculation for \( A_s \) has two parts. The first part is for balancing the compressive force from the flange, \( C_f \), and the second part is for balancing the compressive force from the web, \( C_w \), as shown in Figure 15-2.

\[ C_f \text{ is given by:} \]
Therefore, \( A_{sl} = \frac{C_f}{f_y} \) and the portion of \( M^* \) that is resisted by the flange is given by:

\[
M_f^* = C_f \left( d - \frac{d_1}{2} \right) \phi_b
\]

Therefore, the balance of the moment, \( M^* \), to be carried by the web is:

\[
M_w^* = M^* - M_f^*
\]

The web is a rectangular section with dimensions \( b_w \) and \( d \), for which the depth of the compression block is recalculated as:

\[
a_1 = d - \sqrt{d^2 - \frac{2M_w^*}{\alpha_c f_c^* \phi_b b_w}}
\]

(NZS 7.4.2)

- If \( a_1 \leq a_{\text{max}} \) (NZS 9.3.8.1), the area of tension reinforcement is then given by:

\[
A_{s2} = \frac{M_w^*}{\phi_b f_y \left( d - \frac{a_1}{2} \right)} , \text{ and}
\]

\[
A_s = A_{sl} + A_{s2}
\]

This reinforcement is to be placed at the bottom of the flanged section.

- If \( a_1 > a_{\text{max}} \) (NZS 9.3.8.1), compression reinforcement is required and is calculated as follows:

The compressive force in the web concrete alone is given by:

\[
C_w = \alpha_c f_c^* b_w a_{\text{max}}
\]

(NZS 7.4.2.7)

and the moment resisted by the concrete web and tension reinforcement is:
\[ M_c^* = C_w \left( d - \frac{a_{\text{max}}}{2} \right) \phi_b \]

The moment resisted by compression and tension reinforcement is:

\[ M_s^* = M_w^* - M_c^* \]

Therefore, the compression reinforcement is computed as:

\[ A_c' = \frac{M_s^*}{(f_s' - \alpha f_c^*)(d - d') \phi_b}, \text{ where} \]

\[ f_s' = \epsilon_{c,\text{max}} E_s \left[ \frac{c-d'}{e} \right] \leq f_y \quad \text{(NZS 7.4.2.2, 7.4.2.4)} \]

The tension reinforcement for balancing compression in the web concrete is:

\[ A_s2 = \frac{M_c^*}{f_y (d - \frac{a_{\text{max}}}{2}) \phi_b} \]

and the tension reinforcement for balancing the compression reinforcement is:

\[ A_s3 = \frac{M_s^*}{f_y (d - d') \phi_b} \]

Total tension reinforcement is \( A_s = A_s2 + A_s3 \), and the total compression reinforcement is \( A_c' \). \( A_c' \) is to be placed at the bottom, and \( A_s \) is to be placed at the top.

### 15.5.3.2 Minimum and Maximum Reinforcement

The minimum flexural tension reinforcement required for each direction of a slab is given by the following limit (NZS 12.5.6.2, 8.8, 2.4.4):

\[ A_s \geq \begin{cases} 
0.7 \frac{bh}{f_y} & f_y < 500 \text{ MPa} \\
0.0014bh & f_y \geq 500 \text{ MPa} 
\end{cases} \quad \text{(NZS 12.5.6.2, 8.8.1)} \]
In addition, an upper limit on both the tension reinforcement and compression reinforcement has been imposed to be 0.04 times the gross cross-sectional area.

The slab reinforcement requirements reported by the program do not consider crack control. Any minimum requirements to satisfy crack limitations must be investigated independently of the program by the user.

### 15.5.2 Design Slab Shear Reinforcement

The shear reinforcement is designed for each load combination at each station along the design strip. In designing the shear reinforcement for a particular strip, for a particular load combination, at a particular station due to the slab major shear, the following steps are involved:

- Determine the factored shear force, \( V' \).
- Determine the shear force, \( V_c \), that can be resisted by the concrete.
- Determine the shear reinforcement required to carry the balance.

The following three sections describe in detail the algorithms associated with these steps.

#### 15.5.3.2 Determine Shear Force and Moment

In the design of the slab shear reinforcement, the shear forces for each load combination at a particular slab section are obtained by factoring the corresponding shear forces for different load cases with the corresponding load combination factors.

#### 15.5.3.2 Determine Concrete Shear Capacity

The shear force carried by the concrete, \( V_c \), is calculated as:

\[
V_c = v_c A_{cv}
\]  

(NZS 9.3.9.3.4)

The allowable shear stress capacity is given by:

\[
v_c = k_d k_e k_n v_b
\]  

(NZS 9.3.9.3.4)

The basic shear strength for a rectangular section is computed as,
\[ \nu_b = \left[ 0.07 + 10 \frac{A_v}{b_u d} \right] \lambda \sqrt{f'_c}, \text{ where} \] 
(NZS 9.3.9.3.4)

\[ f'_c \leq 50 \text{ MPa}, \text{ and} \] 
(NZS 9.3.9.3.4)

\[ 0.08 \lambda \sqrt{f'_c} \leq \nu_b \leq 0.2 \lambda \sqrt{f'_c} \] 
(NZS 9.3.9.3.4)

where

\[ \lambda = \begin{cases} 
1.0, & \text{normal concrete} \\
0.85, & \text{sand light-weight concrete} \\
0.75, & \text{all light-weight concrete} 
\end{cases} \] 
(NZS 9.3.9.3.5)

The factor \( k_a \) allows for the influence of maximum aggregate size on shear strength. For concrete with a maximum aggregate size of 20 mm or more, \( k_a \) shall be taken as 1.0. For concrete where the maximum aggregate size is 10 mm or less, the value of \( k_a \) shall be taken as 0.85. Interpolation is used between these limits. The program default for \( k_a \) is 1.0.

\[ k_a = \begin{cases} 
0.85, & a_g \leq 10 \text{ mm} \\
0.85 + 0.15 \left( \frac{a_g - 10}{20} \right), & a_g < 20 \text{ mm} \\
1.00, & a_g \geq 20 \text{ mm} 
\end{cases} \] 
(NZS 9.3.9.3.4)

The factor \( k_d \) allows for the influence of member depth on strength and it shall be calculated from the following conditions:

For members with shear reinforcement equal to or greater than the nominal shear reinforcement given in NZS 9.3.9.4.15, \( k_d = 1.0 \)

For members with an effective depth equal to or smaller than 400 mm, \( k_d = 1.0 \) (NZS 9.3.9.3.4)

For members with an effective depth greater than 400, \( k_d = \left( \frac{400}{d} \right)^{0.25} \)

where \( d \) is in mm (NZS 9.3.9.3.4)

The factor \( k_n \) allows for the influence of axial loading (NZS 10.3.10.3.1).
15.5.3.2 Determine Required Shear Reinforcement

The average shear stress is computed for rectangular and flanged sections as:

$$v^* = \frac{V^*}{b_w d}$$  \hspace{1cm} (NZS 7.5.1)

The average shear stress is limited to a maximum of,

$$v_{\text{max}} = \min \{0.2f'_c, 8 \text{ MPa}\}$$  \hspace{1cm} (NZS 7.5.2, 9.3.9.3.3)

The shear reinforcement is computed as follows:

- If $$v^* \leq \phi_s \left(\frac{v_c}{2}\right)$$ or $$h \leq \max(300 \text{ mm}, 0.5b_w)$$,

  $$\frac{A_v}{s} = 0$$  \hspace{1cm} (NZS 9.3.9.4.13)

- If $$\phi_s \left(\frac{v_c}{2}\right) < v^* \leq \phi_s v_c$$,

  $$\frac{A_v}{s} = \frac{1}{16} \sqrt{f'_c b_w}$$  \hspace{1cm} (NZS 7.5.10, 9.3.9.4.15)

- If $$\phi_s v_c < v^* \leq \phi_s v_{\text{max}}$$,  \hspace{1cm} (NZS 9.3.9.4.2)

  $$\frac{A_v}{s} = \frac{\left(v^* - \phi_s v_c\right)}{\phi_s f_y d}$$

- If $$v^* > v_{\text{max}}$$, a failure condition is declared.  \hspace{1cm} (NZS 7.5.2, 9.3.9.3.3)
If the slab depth $h$ is less than the minimum of 300 mm and $0.5b_w$, no shear reinforcement is required (NZS 9.3.9.4.13).

The maximum of all of the calculated $A_{sv}/s$ values, obtained from each load combination, is reported along with the controlling shear force and associated load combination.

The slab shear reinforcement requirements considered by the program are based purely on shear strength considerations. Any minimum stirrup requirements to satisfy spacing and volumetric considerations must be investigated independently of the program by the user.

### 15.5.3 Check for Punching Shear

The algorithm for checking punching shear is detailed in the section entitled “Slab Punching Shear Check” in the Key Features and Terminology manual. Only the code-specific items are described in the following.

#### 15.5.3.1 Critical Section for Punching Shear

The punching shear is checked on a critical section at a distance of $d/2$ from the face of the support (NZS 12.7.1(b)). For rectangular columns and concentrated loads, the critical area is taken as a rectangular area with the sides parallel to the sides of the columns or the point loads (NZS 12.7.1(b)). Figure 15-3 shows the auto punching perimeters considered by ETABS for the various column shapes. The column location (i.e., interior, edge, corner) and the punching perimeter may be overwritten using the Punching Check Overwrites.
15.5.3.2 Transfer of Unbalanced Moment

The fraction of unbalanced moment transferred by flexure is taken to be $\gamma_f M^*$ and the fraction of unbalanced moment transferred by eccentricity of shear is taken to be $\gamma_v M^*$, where

$$\gamma_f = \frac{1}{1 + (2/3)\sqrt{b_1/b_2}}$$  \hspace{1cm} (NZS 12.7.7.2)

$$\gamma_v = 1 - \frac{1}{1 + (2/3)\sqrt{b_1/b_2}}$$  \hspace{1cm} (NZS 12.7.7.1)

where $b_1$ is the width of the critical section measured in the direction of the span and $b_2$ is the width of the critical section measured in the direction perpendicular to the span.

15.5.3.3 Determination of Concrete Capacity

The concrete punching shear factored strength is taken as the minimum of the following three limits:
\[
\nu_v = \min\left\{ \frac{1}{6} \left( 1 + \frac{2}{\beta_c} \right) \sqrt{f'_c}, \frac{1}{6} \left( 1 + \frac{\alpha_s d}{b_0} \right) \sqrt{f'_c}, \frac{1}{3} \sqrt{f'_c} \right\}
\]

(NZS 12.7.3.2)

where, \( \beta_c \) is the ratio of the maximum to the minimum dimension of the critical section (NZS 12.1, 12.7.3.2(a)), \( b_0 \) is the perimeter of the critical section, and \( \alpha_s \) is a scale factor based on the location of the critical section.

\[
\alpha_s = \begin{cases} 
20 & \text{for interior columns,} \\
15 & \text{for edge columns,} \\
10 & \text{for corner columns.}
\end{cases}
\]

(NZS 12.7.3.2(b))

A limit is imposed on the value of \( \sqrt{f'_c} \) as follows:

\[
\lambda \sqrt{f'_c} \leq \sqrt{100}
\]

(NZS 9.3.9.3.5(6))

### 15.5.3.4 Determine Maximum Shear Stress

Given the punching shear force and the fractions of moments transferred by eccentricity of shear about the two axes, the shear stress is computed assuming linear variation along the perimeter of the critical section.

\[
\nu_v = \frac{V'}{bod} + \gamma V_2 \left[ M_2^* - V^* (y_3 - y_1) \right] \frac{I_{33} (y_4 - y_3) - I_{23} (x_4 - x_3)}{I_{23}^2 - I_{23}^2} \]

\[
\gamma V_3 \left[ M_3^* - V^* (x_3 - x_1) \right] \frac{I_{23} (y_4 - y_3) - I_{23} (y_4 - y_3)}{I_{23}^2 - I_{23}^2}
\]

Eq. 1

\[
I_{22} = \sum_{sides=1}^{n} I'_{22} \text{, where "sides" refers to the sides of the critical section for punching shear}
\]

Eq. 2

---

\( \gamma \)
\[ I_{33} = \sum_{sides=1}^{n} T_{33}, \quad \text{where "sides" refers to the sides of the critical section for punching shear} \quad \text{Eq. 3} \]

\[ I_{23} = \sum_{sides=1}^{n} T_{23}, \quad \text{where "sides" refers to the sides of the critical section for punching shear} \quad \text{Eq. 4} \]

The equations for \( T_{22}, T_{33}, \) and \( T_{23} \) are different depending on whether the side of the critical section for punching shear being considered is parallel to the 2-axis or parallel to the 3-axis. Refer to Figures 15-4.

\[ T_{22} = Ld(y_2 - y_3)^2, \quad \text{for side of critical section parallel to 2-axis} \quad \text{Eq. 5a} \]

\[ T_{22} = \frac{Ld^3}{12} + \frac{dL^3}{12} + Ld(y_2 - y_3)^2, \quad \text{for the side of the critical section parallel to the 3-axis} \quad \text{Eq. 5b} \]
Chapter 15 - Design for NZS 3101-06

Figure 15-4 Shear Stress Calculations at Critical Sections

\[ T_{33} = \frac{Ld^3}{12} + \frac{dL^3}{12} + Ld(x_2 - y_3)^3, \text{ for the side of the critical section parallel to the 2-axis} \]

Eq. 6

\[ T_{33} = Ld(x_2 - x_3)^2, \text{ for the side of the critical section parallel to the 3-axis} \]

Eq. 6b

\[ T_{23} = Ld(x_2 - x_3)(y_2 - y_3), \text{ for the side of the critical section parallel to the 2-axis or 3-axis} \]

Eq. 7

NOTE: \( T_{23} \) is explicitly set to zero for corner condition.
where,

\[ b_0 \] = Perimeter of critical section for punching shear

\[ d \] = Effective depth at critical section for punching shear based on average of \( d \) for 2 direction and \( d \) for 3 direction

\[ I_{22} \] = Moment of inertia of critical section for punching shear about an axis that is parallel to the local 2-axis

\[ I_{33} \] = Moment of inertia of critical section for punching shear about an axis that is parallel to the local 3-axis

\[ I_{23} \] = Product of inertia of critical section for punching shear with respect to the 2 and 3 planes

\[ L \] = Length of the side of the critical section for punching shear currently being considered

\[ M'_2 \] = Moment about line parallel to 2-axis at center of column (positive per right-hand rule)

\[ M'_3 \] = Moment about line parallel to 3-axis at center of column (positive per right-hand rule)

\[ V^* \] = Punching shear stress

\[ V^* \] = Shear at center of column (positive upward)

\[ x_1, y_1 \] = Coordinates of column centroid

\[ x_2, y_2 \] = Coordinates of center of one side of critical section for punching shear

\[ x_3, y_3 \] = Coordinates of centroid of critical section for punching shear

\[ x_4, y_4 \] = Coordinates of location where you are calculating stress

\[ \gamma_{v2} \] = Percent of \( M_{U2} \) resisted by shear

\[ \gamma_{v3} \] = Percent of \( M_{U3} \) resisted by shear
15.5.3.5 Determine Capacity Ratio

The ratio of the maximum shear stress and the concrete punching shear stress capacity is reported as the punching shear capacity ratio by ETABS. If this ratio exceeds 1.0, punching shear reinforcement is designed as described in the following section.

15.5.4 Design Punching Shear Reinforcement

The use of shear studs as shear reinforcement in slabs is permitted, provided that the effective depth of the slab is greater than or equal to 150 mm, and not less than 16 times the shear reinforcement bar diameter (NZS 12.7.4.1). If the slab thickness does not meet these requirements, the punching shear reinforcement is not designed and the slab thickness should be increased by the user.

The algorithm for designing the required punching shear reinforcement is used when the punching shear capacity ratio exceeds unity. The Critical Section for Punching Shear and Transfer of Unbalanced Moment as described in the earlier sections remain unchanged. The design of punching shear reinforcement is performed as described in the subsections that follow.

15.5.4.1 Determine Concrete Shear Capacity

The concrete punching shear stress capacity of a section with punching shear reinforcement is determined as:

\[ v_c = \frac{1}{6} \sqrt{f'_c} \]  
(NZS 12.7.3.5)

15.5.4.2 Determine Required Shear Reinforcement

The shear force is limited to a maximum of:

\[ v_{\text{max}} = 0.5 \sqrt{f'_c} \]  
(NZS 12.7.3.4)

Given \( v^*, v_c, \) and \( v_{\text{max}} \), the required shear reinforcement is calculated as follows, where, \( \phi \) is the strength reduction factor.
\[ \frac{A_v}{s} = \frac{(v_n - v_c)}{\phi f_{ys}d} \]  
(NZS 12.7.4.2(a))

Minimum punching shear reinforcement should be provided such that:

\[ V_s \geq \frac{1}{16} \sqrt{f_{c}^{'} b_o d} \]  
(NZS 12.7.4.3)

- If \( v_n > \phi v_{\max} \), a failure condition is declared. (NZS 12.7.3.4)
- If \( v_n \) exceeds the maximum permitted value of \( \phi v_{\max} \), the concrete section should be increased in size.

### 15.5.4.3 Determine Reinforcement Arrangement

Punching shear reinforcement in the vicinity of rectangular columns should be arranged on peripheral lines, i.e., lines running parallel to and at constant distances from the sides of the column. Figure 15-5 shows a typical arrangement of shear reinforcement in the vicinity of a rectangular interior, edge, and corner column.

Figure 15-5 Typical arrangement of shear studs and critical sections outside shear-reinforced zone

The distance between the column face and the first line of shear reinforcement shall not exceed \( d/2 \). The spacing between adjacent shear reinforcement in the
first line (perimeter) of shear reinforcement shall not exceed $2d$ measured in a direction parallel to the column face (NZS 12.7.4.4).

Punching shear reinforcement is most effective near column corners where there are concentrations of shear stress. Therefore, the minimum number of lines of shear reinforcement is 4, 6, and 8, for corner, edge, and interior columns respectively.

15.5.4.4 Determine Reinforcement Diameter, Height, and Spacing

The punching shear reinforcement is most effective when the anchorage is close to the top and bottom surfaces of the slab. The cover of anchors should not be less than the minimum cover specified in NZS 3.11 plus half of the diameter of the flexural reinforcement.

When specifying shear studs, the distance, $s_o$, between the column face and the first peripheral line of shear studs should not be smaller than $0.5d$. The spacing between adjacent shear studs, $g$, at the first peripheral line of studs shall not exceed $2d$ and in the case of studs in a radial pattern, the angle between adjacent stud rails shall not exceed 60 degrees. The limits of $s_o$ and the spacing, $s$, between the peripheral lines are specified as:

$$s_o \leq 0.5d \quad (NZS\ 12.7.4.4)$$
$$s \leq 0.5d \quad (NZS\ 12.7.4.4)$$
$$g \leq 2d \quad (NZS\ 12.7.4.4)$$
Chapter 16
Design for Singapore CP 65-99

This chapter describes in detail the various aspects of the concrete design procedure that is used by ETABS when the Singapore standard, Structural Use of Concrete code CP 65-99 [CP 99], is selected. The program also includes the recommendations of BC 2:2008 Design Guide of High Strength Concrete to Singapore Standard CP65 [BC 2008]. Various notations used in this chapter are listed in Table 16-1. For referencing to the pertinent sections of the Singapore code in this chapter, a prefix “CP” followed by the section number is used.

The design is based on user-specified load combinations. The program provides a set of default load combinations that should satisfy the requirements for the design of most building type structures.

English as well as SI and MKS metric units can be used for input. The code is based on Newton-millimeter-second units. For simplicity, all equations and descriptions presented in this chapter correspond to Newton-millimeter-second units unless otherwise noted.

16.2 Design Load Combinations

The design load combinations are the various combinations of the load cases for which the structure needs to be designed. The design load combinations are obtained by multiplying the characteristic loads by appropriate partial factors of safety, $\gamma_f$ (CP 2.4.1.3). If a structure is subjected to dead (D), live (L), pattern live (PL), and wind (W) loads, and considering that wind forces are reversible, the following load combinations may need to be considered (CP 2.4.3).

1. $1.4D$
2. $1.4D + 1.6L$
3. $1.4D + 1.6(0.75PL)$
4. $1.0D \pm 1.4W$
5. $1.4D \pm 1.4W$
6. $1.2D + 1.2L \pm 1.2W$

These are also the default design load combinations in ETABS whenever the CP 65-99 code is used. If roof live load is treated separately or other types of loads are present, other appropriate load combinations should be used. Note that the automatic combination, including pattern live load, is assumed and should be reviewed before using for design.

16.3 Limits on Material Strength

The concrete compressive strength, $f_{cu}$, should not be less than 30 MPa (CP 3.1.7.2).

The program does not enforce this limit for flexure and shear design of slabs. The input material strengths are used for design even if they are outside of the limits. It is the user's responsibility to use the proper strength values while defining the materials.

16.4 Partial Safety Factors

The design strengths for concrete and reinforcement are obtained by dividing the characteristic strength of the material by a partial safety factor, $\gamma_m$. The
values of $\gamma_m$ used in the program are listed in the table that follows and are taken from CP Table 2.2 (CP 2.4.4.1):

<table>
<thead>
<tr>
<th>Values of $\gamma_m$ for the Ultimate Limit State</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Reinforcement</td>
<td>1.15</td>
</tr>
<tr>
<td>Concrete in flexure and axial load</td>
<td>1.50</td>
</tr>
<tr>
<td>Concrete shear strength without shear reinforcement</td>
<td>1.25</td>
</tr>
</tbody>
</table>

These factors are incorporated into the design equations and tables in the code, but can be overwritten.

16.5 **Slab Design**

ETABS slab design procedure involves defining sets of strips in two mutually perpendicular directions. The locations of the strips are usually governed by the locations of the slab supports. The axial force, moments and shears for a particular strip are recovered from the analysis (on the basis of the Wood-Armer technique), and a flexural design is carried out based on the ultimate strength design method.

The slab design procedure involves the following steps:

- Design flexural reinforcement
- Design shear reinforcement
- Punching check

16.5.1 **Design Flexural Reinforcement**

For slabs, ETABS uses either design strips or the finite element based design to calculate the slab flexural reinforcement in accordance with the selected design code. For simplicity, only strip-by-strip design is documented in the proceeding sections.

The design of the slab reinforcement for a particular strip is carried out at specific locations along the length of the strip. These locations correspond to the element
ETABS Reinforced Concrete Design

boundaries. Controlling reinforcement is computed on either side of those element boundaries. The slab flexural design procedure for each load combination involves the following:

- Determine factored axial loads and moments for each slab strip.
- Design flexural reinforcement for the strip.
- These two steps, described in the text that follows, are repeated for every load combination. The maximum reinforcement calculated for the top and bottom of the slab within each design strip, along with the corresponding controlling load combination, is obtained and reported.

16.5.1.1 Determine Factored Moments
In the design of flexural reinforcement of concrete slab, the factored moments for each load combination at a particular design strip are obtained by factoring the corresponding moments for different load cases, with the corresponding load factors.

The slab is then designed for the maximum positive and maximum negative factored moments obtained from all of the load combinations. Calculation of bottom reinforcement is based on positive design strip moments. In such cases, the slab may be designed as a rectangular or flanged slab section. Calculation of top reinforcement is based on negative design strip moments. In such cases, the slab may be designed as a rectangular or inverted flanged slab section.

16.5.1.2 Determine Required Flexural Reinforcement
In the flexural reinforcement design process, the program calculates both the tension and compression reinforcement. Compression reinforcement is added when the applied design moment exceeds the maximum moment capacity of a singly reinforced section. The user has the option of avoiding the compression reinforcement by increasing the effective depth, the width, or the strength of the concrete.

The design procedure is based on the simplified rectangular stress block shown in Figure 16-1 (CP 3.4.4.4), where ε is defined as:
Furthermore, it is assumed that moment redistribution in the member does not exceed 10% (i.e., \( \beta_b \geq 0.9 \); CP 3.4.4.4). The code also places a limitation on the neutral axis depth,

\[
\frac{x}{d} \leq \begin{cases} 
0.5 & \text{for } f_{cu} \leq 60 \text{ N/mm}^2 \\
0.4 & \text{for } 60 < f_{cu} \leq 75 \text{ N/mm}^2 \\
0.33 & \text{for } 75 < f_{cu} \leq 105 \text{ N/mm}^2 
\end{cases} \quad (\text{CP 3.4.4.4, BC 2.2})
\]

to safeguard against non-ductile failures (CP 3.4.4.4). In addition, the area of compression reinforcement is calculated assuming that the neutral axis depth remains at the maximum permitted value.

The depth of the compression block is given by:

\[
a = \begin{cases} 
0.9x & \text{for } f_{cu} \leq 60 \text{ N/mm}^2 \\
0.8x & \text{for } 60 < f_{cu} \leq 75 \text{ N/mm}^2 \\
0.72x & \text{for } 75 < f_{cu} \leq 105 \text{ N/mm}^2 
\end{cases} \quad (\text{CP 3.4.4.4, BC 2.2})
\]

The design procedure used by ETABS, for both rectangular and flanged sections (L- and T-shaped sections), is summarized in the text that follows. For reinforced concrete design where design ultimate axial compression load does not exceed \( (0.1 f_{cu} A_g) \) (CP 3.4.4.1), axial force is ignored; hence, all slabs are designed for major direction flexure and shear only. Axial compression greater than \( 0.1 f_{cu} A_g \) and axial tensions are always included in flexural and shear design.

### 16.5.1.2.1 Design of uniform thickness slab

For uniform thickness slab, the limiting moment capacity as a singly reinforced slab, \( M_{\text{single}} \), is first calculated for a section. The reinforcement is determined based on whether \( M \) is greater than, less than, or equal to \( M_{\text{single}} \). See Figure 16-1.
Calculate the ultimate limiting moment of resistance of the section as singly reinforced.

\[ M_{\text{single}} = K' f_{cu} bd^2, \]

where \( K' \) is given by

\[
K' = \begin{cases} 
0.156 & \text{for} \quad f_{cu} \leq 60 \text{ N/mm}^2 \\
0.120 & \text{for} \quad 60 < f_{cu} \leq 75 \text{ N/mm}^2 \\
0.094 & \text{for} \quad 75 < f_{cu} \leq 105 \text{ N/mm}^2 \quad \text{and no moment redistribution.}
\end{cases}
\]

- If \( M \leq M_{\text{single}} \), the area of tension reinforcement, \( A_s \), is given by:

\[ A_s = \frac{M}{0.87 f_y z}, \]

where \( f_y \) is the yield strength of the reinforcement, and \( z \) is the distance from the tension face to the point of interest.

---

Figure 16-1 Uniform Thickness Slab Design
This reinforcement is to be placed at the bottom if $M$ is positive, or at the top if $M$ is negative.

- If $M > M_{\text{single}}$, compression reinforcement is required and calculated as follows:

$$A'_{\text{s}} = \frac{M - M_{\text{single}}}{f'_{\text{s}} - \frac{0.67 f_{\text{cu}}}{\gamma_m}} (d - d') \quad (CP 3.4.4.4)$$

where $d'$ is the depth of the compression reinforcement from the concrete compression face, and

$$f'_{\text{s}} = 0.87 f_y \quad \text{if } \frac{d'}{d} \leq \frac{1}{2} \left[ 1 - \frac{f_y}{800} \right] \quad (CP 3.4.4.1, 2.5.3, \text{Fig 2.2})$$

$$f'_{\text{s}} = E_{\text{s}} \epsilon_c \left[ 1 - \frac{2d'}{d} \right] \quad \text{if } \frac{d'}{d} > \frac{1}{2} \left[ 1 - \frac{f_y}{800} \right] \quad (CP 3.4.4.4, 2.5.3, \text{Fig 2.2})$$

The tension reinforcement required for balancing the compression in the concrete and the compression reinforcement is calculated as:

$$A_t = \frac{M_{\text{single}}}{0.87 f_y z} + \frac{M - M_{\text{single}}}{0.87 f_y (d - d')} \quad \text{where} \quad (CP 3.4.4.4)$$

$$z = d \left( 0.5 + \sqrt{0.25 - \frac{K'}{0.9}} \right) \leq 0.95d \quad (CP 3.4.4.4)$$
16.5.1.2.2 Design of nonuniform thickness slab

16.5.1.2.2.1 Flanged Slab Section Under Negative Moment
In designing for a factored negative moment, \( M \) (i.e., designing top reinforcement), the calculation of the reinforcement area is exactly the same as described previously, i.e., no flanged data is used.

16.5.1.2.2.2 Flanged Slab Section Under Positive Moment
With the flange in compression, the program analyzes the section by considering alternative locations of the neutral axis. Initially the neutral axis is assumed to be located in the flange. On the basis of this assumption, the program calculates the exact depth of the neutral axis. If the stress block does not extend beyond the flange thickness, the section is designed as a uniform thickness slab of width \( b_f \).

If the stress block extends beyond the flange width, the contribution of the web to the flexural strength of the slab is taken into account. See Figure 16-2.

![Figure 16-2 Nonuniform Thickness Slab Design](image)

Assuming the neutral axis to lie in the flange, the normalized moment is given by:

16 - 10  Slab Design
Chapter 16 - Design for Singapore CP 65-99

\[ K = \frac{M}{f_{cu} b_f d^2} \]  
\text{(CP 3.4.4.4)}

Then the moment arm is computed as:
\[ z = d \left\{ 0.5 + \sqrt{0.25 - \frac{K}{0.9}} \right\} \leq 0.95d \]  
\text{(CP 3.4.4.4)}

the depth of neutral axis is computed as:
\[
x = \begin{cases} 
\frac{d-z}{0.45} & \text{for } f_{cu} \leq 60 \text{N/mm}^2 \\
\frac{d-z}{0.40} & \text{for } 60 < f_{cu} \leq 75 \text{N/mm}^2 \\
\frac{d-z}{0.36} & \text{for } 75 < f_{cu} \leq 105 \text{N/mm}^2 
\end{cases}
\text{(CP 3.4.4.4, BC 2.2, Fig 2.3)}

and the depth of the compression block is given by:
\[
a = \begin{cases} 
0.9x & \text{for } f_{cu} \leq 60 \text{N/mm}^2 \\
0.8x & \text{for } 60 < f_{cu} \leq 75 \text{N/mm}^2 \\
0.72x & \text{for } 75 < f_{cu} \leq 105 \text{N/mm}^2 
\end{cases}
\text{(CP 3.4.4.4, BC 2.2, Fig 2.3)}

- If \( a \leq h_f \), the subsequent calculations for \( A_s \) are exactly the same as previously defined for the uniform thickness slab design. However, in this case the width of the slab is taken as \( b_f \). Compression reinforcement is required when \( K > K' \).

- If \( a > h_f \),

If \( M \leq \beta f_{cu} b_f d^2 \) and \( h_f \leq 0.45d \) then,
\[
A_s = \frac{M + 0.1 f_{cu} b_d (0.45d - h_f)}{0.87 f_s (d - 0.5h_f)}, \text{ where} \]  
\text{(BS 3.4.4.5)}

\[
\beta_f = 0.45 \frac{h_f}{d} \left( 1 - \frac{b_w}{b} \right) \left( 1 - \frac{h_f}{2d} \right) + 0.15 \frac{b_w}{b} \]  
\text{(BS 3.4.4.5)}
Otherwise the calculation for $A_s$ has two parts. The first part is for balancing the compressive force from the flange, $C_f$, and the second part is for balancing the compressive force from the web, $C_w$, as shown in Figure 16-2.

In that case, the ultimate resistance moment of the flange is given by:

$$M_f = 0.45 f_{cu} \left( b_f - b_w \right) h_f \left( d - 0.5 h_f \right)$$  \hspace{1cm} \text{(CP 3.4.4.5)}

The moment taken by the web is computed as:

$$M_w = M - M_f$$

and the normalized moment resisted by the web is given by:

$$K_w = \frac{M_w}{f_{cu} b_w d^2}$$  \hspace{1cm} \text{(CP 3.4.4.4)}

- If $K_w \leq 0.156$ (CP 3.4.4.4), the slab is designed as a singly reinforced concrete slab. The reinforcement is calculated as the sum of two parts, one to balance compression in the flange and one to balance compression in the web.

$$A_s = \frac{M_f}{0.87 f_y (d - 0.5 h_f)} + \frac{M_w}{0.87 f_y z}$$, where

$$z = d \left( 0.5 + \sqrt{0.25 - \frac{K_w}{0.9}} \right) \leq 0.95d$$

- If $K_w > K'$ (CP 3.4.4.4), compression reinforcement is required and is calculated as follows:

The ultimate moment of resistance of the web only is given by:

$$M_{uw} = K' f_{cu} b_w d^2$$  \hspace{1cm} \text{(CP 3.4.4.4)}

The compression reinforcement is required to resist a moment of magnitude $M_w - M_{uw}$. The compression reinforcement is computed as:
where, \(d'\) is the depth of the compression reinforcement from the concrete compression face, and

\[
f'_s = 0.87 f_y \quad \text{if} \quad \frac{d'}{d} \leq \frac{1}{2} \left[1 - \frac{f_y}{800}\right] \quad \text{(CP 3.4.4.4, 2.5.3, Fig 2.2)}
\]

\[
f'_s = E_s \epsilon_c \left[1 - \frac{2d'}{d}\right] \quad \text{if} \quad \frac{d'}{d} > \frac{1}{2} \left[1 - \frac{f_y}{800}\right] \quad \text{(CP 3.4.4.4, 2.5.3, Fig 2.2)}
\]

The area of tension reinforcement is obtained from equilibrium as:

\[
A_s = \frac{1}{0.87 f_y} \left[ \frac{M_f}{d - 0.5 h_f} + \frac{M_{uw}}{z} + \frac{M_w - M_{uw}}{d - d'} \right]
\]

\[
z = d \left(0.5 + \sqrt{0.25 - \frac{K'}{0.9}}\right) \leq 0.95d
\]

### 16.5.1.3 Minimum and Maximum Reinforcement

The minimum flexural tension reinforcement required for each direction of a slab is given by the following limit (CP 3.12.5.3, CP Table 3.25) with interpolation for reinforcement of intermediate strength:

\[
A_s \geq \begin{cases} 
0.0024 bh & \text{if} \quad f_y = 250 \text{ MPa} \\
0.0013 bh & \text{if} \quad f_y = 460 \text{ MPa} 
\end{cases} \quad \text{(CP 3.12.5.3)}
\]

For \(f_{cu} > 40 \text{ N/mm}^2\), the preceding minimum reinforcement shall be multiplied by \((f_{cu}/40)^{2/3}\).

In addition, an upper limit on both the tension reinforcement and compression reinforcement has been imposed to be 0.04 times the gross cross-sectional area (CP 3.12.6.1).
16.5.2  Design Slab Shear Reinforcement

The shear reinforcement is designed for each load combination at each station along the design strip. In designing the shear reinforcement for a particular strip, for a particular load combination, at a particular station due to the slab major shear, the following steps are involved (CP 3.4.5):

- Determine the shear stress, $v$.
- Determine the shear stress, $v_c$, that can be resisted by the concrete.
- Determine the shear reinforcement required to carry the balance.

The following three sections describe in detail the algorithms associated with these steps.

16.5.2.1  Determine Shear Stress

In the design of the slab shear reinforcement, the shear forces for each load combination at a particular strip station are obtained by factoring the corresponding shear forces for different load cases with the corresponding load combination factors. The shear stress is then calculated as:

$$ v = \frac{V}{b_w d} $$

The maximum allowable shear stress, $v_{max}$, is defined as:

$$ v_{max} = \min (0.8 \sqrt{f_{cu}}, 7 \text{ MPa}). $$

For light-weight concrete, $v_{max}$ is defined as:

$$ v_{max} = \min (0.63 \sqrt{f_{cu}}, 4 \text{ MPa}) $$

16.5.2.2  Determine Concrete Shear Capacity

The shear stress carried by the concrete, $v_c$, is calculated as:
$v'_c = v_c + 0.6 \frac{NVh}{A_eM} \leq v_c \sqrt{1 + \frac{N}{A_e v_c}}$  \hspace{1cm} (CP 3.4.5.12)

$v_c = \frac{0.84k_1k_2}{\gamma_m} \left( \frac{100A_e}{bd} \right)^{\frac{1}{5}} \left( \frac{400}{d} \right)^{\frac{1}{4}}$  \hspace{1cm} (CP 3.4.5.4, Table 3.9)

$k_1$ is the enhancement factor for support compression, and is conservatively taken as 1  \hspace{1cm} (CP 3.4.5.8)

$k_2 = \left( \frac{f_{cu}}{30} \right)^{\frac{1}{5}}$, \hspace{0.5cm} 1 \leq k_2 \leq \left( \frac{80}{30} \right)^{\frac{1}{5}}  \hspace{1cm} (CP 3.4.5.4)

$\gamma_m = 1.25$  \hspace{1cm} (CP 2.4.4.1)

However, the following limitations also apply:

$0.15 \leq \frac{100A_e}{bd} \leq 3$  \hspace{1cm} (CP 3.4.5.4, Table 3.9)

$\left( \frac{400}{d} \right)^{\frac{1}{4}} \geq 0.67$ (unreinforced) or $\geq 1$ (reinforced)(CP 3.4.5.4, Table 3.9)

$f_{cu} \leq 80$ MPa (for calculation purpose only)  \hspace{1cm} (CP 3.4.5.4, Table 3.9)

$\frac{Vh}{M} \leq 1$  \hspace{1cm} (CP 3.4.5.12)

$A_t$ is the area of tension reinforcement

16.5.2.3 Determine Required Shear Reinforcement

Given $v$, $v'$, and $v_{max}$, the required shear reinforcement is calculated as follows (CP Table 3.8, CP 3.4.5.3):

- Calculate the design average shear stress that can be carried by minimum shear reinforcement, $v_r$, as:
ETABS Reinforced Concrete Design

- \[ v_r = \begin{cases} 
0.4 & \text{if } f_{cu} \leq 40 \text{N/mm}^2 \\
0.4 \left( \frac{f_{cu}}{40} \right)^{\frac{1}{3}} & \text{if } 40 < f_{cu} \leq 80 \text{N/mm}^2 
\end{cases} \]  
  (CP 3.4.5.3, Table 3.8)

\[ f_{cu} \leq 80 \text{N/mm}^2 \text{ (for calculation purpose only)} \]  
  (CP 3.4.5.3, Table 3.8)

- If \( v \leq v'_c + v_r \),
  \[ A_v = \frac{v_r b}{0.87 f_{vy}} \]  
  (CP 3.4.5.3, Table 3.8)

- If \( v > v'_c + v_r \),
  \[ A_{sv} = \frac{(v - v'_c) b}{0.87 f_{vy}} \]  
  (CP 3.4.5.3, Table 3.8)

- If \( v > v_{max} \), a failure condition is declared.  
  (CP 3.4.5.2)

In the preceding expressions, a limit is imposed on the \( f_{vy} \) as

\[ f_{vy} \leq 460 \text{ MPa} \]  
  (CP 3.4.5.1)

The maximum of all of the calculated \( A_{sv}/s_v \) values, obtained from each load combination, is reported along with the controlling shear force and associated load combination.

The slab shear reinforcement requirements considered by the program are based purely on shear strength considerations. Any minimum stirrup requirements to satisfy spacing and volumetric considerations must be investigated independently of the program by the user.

16.5.3 Check for Punching Shear

The algorithm for checking punching shear is detailed in the section entitled “Slab Punching Shear Check” in the Chapter 1. Only the code-specific items are described in the following sections.
16.5.3.1 Critical Section for Punching Shear

The punching shear is checked on a critical section at a distance of 1.5\(d\) from the face of the support (CP 3.7.7.4, 3.7.7.6). For rectangular columns and concentrated loads, the critical area is taken as a rectangular area with the sides parallel to the sides of the columns or the point loads (CP 3.7.7.1). Figure 16-3 shows the auto punching perimeters considered by ETABS for the various column shapes. The column location (i.e., interior, edge, corner) and the punching perimeter may be overwritten using the Punching Check Overwrites.

16.5.3.2 Determination of Concrete Capacity

The concrete punching shear factored strength is taken as (CP 3.7.7.4, 3.7.7.6):

\[
v_c = \frac{0.84k_1k_2}{\gamma_m} \left( \frac{100A_s}{bd} \right)^{1/2} \left( \frac{400}{d} \right)^{1/4}
\]

(CP 3.4.5.4, Table 3.9)

\(k_1\) is the enhancement factor for support compression, and is conservatively taken as 1

(CP 3.4.5.8)

![Figure 16-3 Punching Shear Perimeters](image)

Slab Design  16 - 17
\[ k_2 = \left( \frac{f_{cu}}{30} \right)^{\frac{1}{3}} \]

\[ 1 \leq k_2 \leq \left( \frac{80}{30} \right)^{\frac{1}{3}} \]  

(CP 3.4.5.4, Table 3.9)

\[ \gamma_m = 1.25 \]  

(CP 3.4.5.2)

However, the following limitations also apply:

\[ 0.15 \leq \frac{100A_s}{bd} \leq 3 \]  

(CP 3.4.5.4, Table 3.9)

\[ \left( \frac{400}{d} \right)^{\frac{1}{4}} \geq 0.67 \text{ (unreinforced)} \text{ or } \geq 1 \text{ (reinforced)} \]  

(CP 3.4.5.4, Table 3.9)

For light-weight concrete, \( v_{\text{max}} \) is defined as:

\[ v \leq \min(0.63 \sqrt{f_{cu}}, 4 \text{ MPa}) \]  

(CP Part 2 5.4)

\[ v \leq \min(0.8 \sqrt{f_{cu}}, 7 \text{ MPa}) \]  

(CP 3.4.5.2, Table 3.9)

\[ f_{cu} \leq 80 \text{ MPa} \text{ (for calculation purpose only)} \]  

(CP 3.4.5.4, Table 3.9)

\( A_s = \) area of tension reinforcement, which is taken as the average tension reinforcement of design strips in Layer A and layer B where Layer A and Layer design strips are in orthogonal directions. When design strips are not present in both orthogonal directions then tension reinforcement is taken as zero in the current implementation.

### 16.5.3.3 Determine Maximum Shear Stress

Given the punching shear force and the fractions of moments transferred by eccentricity of shear about the two axes, the nominal design shear stress, \( v \), is calculated as:

\[ V_{\text{eff},x} = V \left( f + \frac{1.5M_x}{V_y} \right) \]  

(CP 3.7.6.2, 3.7.6.3)
\[ V_{\text{eff},y} = V \left( f + \frac{1.5M_y}{V_x} \right) \]  
\[ v_{\text{max}} = \max \left\{ \frac{V_{\text{eff},x}}{ud}, \frac{V_{\text{eff},y}}{ud} \right\} \]

where,

- \( u \) is the perimeter of the critical section,
- \( x \) and \( y \) are the lengths of the sides of the critical section parallel to the axis of bending
- \( M_x \) and \( M_y \) are the design moments transmitted from the slab to the column at the connection
- \( V \) is the total punching shear force
- \( f \) is a factor to consider the eccentricity of punching shear force and is taken as:
  \[ f = \begin{cases} 
    1.00 & \text{for interior columns,} \\
    1.25 & \text{for edge columns, and} \\
    1.25 & \text{for corner columns.}
  \end{cases} \]

**16.5.3.4 Determine Capacity Ratio**

The ratio of the maximum shear stress and the concrete punching shear stress capacity is reported as the punching shear capacity ratio by ETABS. If this ratio exceeds 1.0, punching shear reinforcement is designed as described in the following section.

**16.5.4 Design Punching Shear Reinforcement**

The use of shear links as shear reinforcement in slabs is permitted, provided that the effective depth of the slab is greater than or equal to 200 mm (CP 3.7.7.5). If
the slab thickness does not meet this requirement, the punching shear reinforce-
ment is not designed and the slab thickness should be increased by the user.

The algorithm for designing the required punching shear reinforcement is used
when the punching shear capacity ratio exceeds unity. The Critical Section for
Punching Shear and Transfer of Unbalanced Moment as described in the earlier
sections remain unchanged. The design of punching shear reinforcement is com-
pleted as described in the following subsections.

16.5.4.1 Determine Concrete Shear Capacity

The concrete punching shear stress capacity of a section with punching shear
reinforcement is as previously determined for the punching check.

16.5.4.2 Determine Required Shear Reinforcement

The shear stress is limited to a maximum of:

\[ v_{\text{max}} = 2v_c \]  

(CP 3.7.7.5)

Given \( v, v_c \), and \( v_{\text{max}} \), the required shear reinforcement is calculated as follows
(CP 3.7.7.5).

- If \( v \leq 1.6v_c \),

\[ \frac{A_v}{s} = \frac{(v - v_c)ud}{0.87 f_{yy}} \geq \frac{0.4ud}{0.87 f_{yy}}, \]  

(CP 3.7.7.5)

- If \( 1.6v_c \leq v < 2.0v_c \),

\[ \frac{A_v}{s} = \frac{5 \left(0.7v - v_c\right)ud}{0.87 f_{yy}} \geq \frac{0.4ud}{0.87 f_{yy}}, \]  

(CP 3.7.7.5)

- If \( v > v_{\text{max}} \), a failure condition is declared.  

(CP 3.7.7.5)

If \( v \) exceeds the maximum permitted value of \( v_{\text{max}} \), the concrete section should
be increased in size.
16.5.4.3 Determine Reinforcement Arrangement

Punching shear reinforcement in the vicinity of rectangular columns should be arranged on peripheral lines, i.e., lines running parallel to and at constant distances from the sides of the column. Figure 16-4 shows a typical arrangement of shear reinforcement in the vicinity of a rectangular interior, edge, and corner column.

![Diagram showing typical arrangement of shear studs and critical sections outside shear-reinforced zone](image)

The distance between the column face and the first line of shear reinforcement shall not exceed \( \frac{d}{2} \). The spacing between adjacent shear reinforcement in the first line (perimeter) of shear reinforcement shall not exceed \( 1.5d \) measured in a direction parallel to the column face (CP 3.7.7.6).

Punching shear reinforcement is most effective near column corners where there are concentrations of shear stress. Therefore, the minimum number of lines of shear reinforcement is 4, 6, and 8, for corner, edge, and interior columns respectively.

16.5.4.4 Determine Reinforcement Diameter, Height, and Spacing

The punching shear reinforcement is most effective when the anchorage is close to the top and bottom surfaces of the slab. The cover of anchors should not be less than the minimum cover specified in CP 3.3 plus half of the diameter of the flexural reinforcement.
Punching shear reinforcement in the form of shear studs is generally available in 16-, 12-, 14-, 16-, and 20-millimeter diameters.

When specifying shear studs, the distance, $s_o$, between the column face and the first peripheral line of shear studs should not be smaller than $0.5d$. The spacing between adjacent shear studs, $g$, at the first peripheral line of studs shall not exceed $1.5d$. The limits of $s_o$ and the spacing, $s$, between the peripheral lines are specified as:

\[
s_o \leq 0.5d \quad \text{(CP 3.7.7.6)}
\]
\[
s \leq 0.75d \quad \text{(CP 3.7.7.6)}
\]
\[
g \leq 1.5d \quad \text{(CP 3.7.7.6)}
\]
This chapter describes in detail the various aspects of the concrete design procedure that is used by ETABS when the American code TS 500-2000 [TS 500] is selected. Various notations used in this chapter are listed in Table 17-1. For referencing to the pertinent sections or equations of the TS code in this chapter, a prefix “TS” followed by the section or equation number is used herein.

The design is based on user-specified load combinations. The program provides a set of default load combinations that should satisfy the requirements for the design of most building type structures.

English as well as SI and MKS metric units can be used for input. The code is based on Newton-millimeter-second units. For simplicity, all equations and descriptions presented in this chapter correspond to Newton-millimeter-second units unless otherwise noted.

17.2 Design Load Combinations

The design load combinations are the various combinations of the load cases for which the structure needs to be designed. For TS 500-2000, if a structure is subjected to dead (G), live (Q), wind (W), and earthquake (E) loads, and considering that wind and earthquake forces are reversible, the following load combinations may need to be considered (TS 6.2.6):

1. $1.4G + 1.6Q$  
2. $0.9G \pm 1.3W$  
3. $1.0G + 1.3Q \pm 1.3W$  
4. $0.9G \pm 1.0E$  
5. $1.0G + 1.0Q \pm 1.0E$

These are the default design load combinations in ETABS whenever the TS 500-2000 code is used. The user should use other appropriate load combinations if roof live load is treated separately, or if other types of loads are present.
17.3 Limits on Material Strength

The characteristic compressive strength of concrete, \( f_{ck} \), should not be less than 16 N/mm\(^2\). The upper limit of the reinforcement yield stress, \( f_y \), is taken as 420 N/mm\(^2\) and the upper limit of the reinforcement shear strength, \( f_{yk} \), is taken as 420 N/mm\(^2\).

The program enforces the upper material strength limits for flexure and shear design of slab. The input material strengths are taken as the upper limits if they are defined in the material properties as being greater than the limits. The user is responsible for ensuring that the minimum strength is satisfied.

17.4 Design Strength

The design strength for concrete and steel is obtained by dividing the characteristic strength of the material by a partial factor of safety, \( \gamma_{mc} \) and \( \gamma_{ms} \). The values used in the program are as follows:

\[
\gamma_{ms} = 1.15, \quad \text{(TS 6.2.5)}
\]
\[
\gamma_{mc} = 1.5, \quad \text{(TS 6.2.5)}
\]

These factors are already incorporated in the design equations and tables in the code. Although not recommended, the program allows them to be overwritten. If they are overwritten, the program uses them consistently by modifying the code-mandated equations in every relevant place.

17.5 Slab Design

ETABS slab design procedure involves defining sets of strips in two mutually perpendicular directions. The locations of the strips are usually governed by the locations of the slab supports. The axial force, moments and shears for a particular strip are recovered from the analysis (on the basis of the Wood-Armer technique), and a flexural design is carried out based on the ultimate strength design method.

The slab design procedure involves the following steps:

- Design flexural reinforcement
17.5.1 Design Flexural Reinforcement

For slabs, ETABS uses either design strips or the finite element based design to calculate the slab flexural reinforcement in accordance with the selected design code. For simplicity, only strip-by-strip design is documented in the preceding sections.

The design of the slab reinforcement for a particular strip is carried out at specific locations along the length of the strip. These locations correspond to the element boundaries. Controlling reinforcement is computed on either side of those element boundaries. The slab flexural design procedure for each load combination involves the following:

- Determine factored axial loads and moments for each slab strip.
- Design flexural reinforcement for the strip.
- These two steps, described in the text that follows, are repeated for every load combination. The maximum reinforcement calculated for the top and bottom of the slab within each design strip, along with the corresponding controlling load combination, is obtained and reported.

17.5.1.1 Determine Factored Moments

In the design of flexural reinforcement of concrete slab, the factored moments for each load combination at a particular design strip are obtained by factoring the corresponding moments for different load cases, with the corresponding load factors.

The slab is then designed for the maximum positive and maximum negative factored moments obtained from all of the load combinations. Calculation of bottom reinforcement is based on positive design strip moments. In such cases, the slab may be designed as a rectangular or flanged slab section. Calculation of top reinforcement is based on negative design strip moments. In such cases, the slab may be designed as a rectangular or inverted flanged slab section.
17.5.1.2 Determine Required Flexural Reinforcement

In the flexural reinforcement design process, the program calculates both the tension and compression reinforcement. Compression reinforcement is added when the applied design moment exceeds the maximum moment capacity of a singly reinforced section. The user has the option of avoiding the compression reinforcement by increasing the effective depth, the width, or the grade of concrete.

The design procedure is based on the simplified rectangular stress block, as shown in Figure 17-1 (TS 7.1). When the applied moment exceeds the moment capacity at this design condition, the area of compression reinforcement is calculated on the assumption that the additional moment will be carried by compression and additional tension reinforcement.

The design procedure used by the program for both rectangular and flanged sections is summarized in the following subsections. It is assumed that the design ultimate axial force does not exceed \( 0.1f'_{ck}A_g \) (TS 7.3, Eqn. 7.2); hence, all of the slabs are designed ignoring axial force; hence, all slabs are designed for major direction flexure and shear only. Axial compression greater than \( 0.1f'_{ck}A_g \) and axial tensions are always included in flexural and shear design.

17.5.1.2.1 Design of uniform thickness slab

In designing for a factored negative or positive moment, \( M_d \) (i.e., designing top or bottom reinforcement), the depth of the compression block is given by \( a \) (see Figure 17-1), where,

\[
a = d - \sqrt{d^2 - \frac{2|M_d|}{0.85f'_{cd}b}},
\]

(TS 7.1)

The maximum depth of the compression zone, \( c_b \), is calculated based on the compressive strength of the concrete and the tensile steel tension using the following equation (TS 7.1):

\[
c_b = \frac{\varepsilon_{cu}E_s}{\varepsilon_{cu}E_s + f_{yd}}d
\]

(TS 7.1)
The maximum allowable depth of the rectangular compression block, $a_{\text{max}}$, is given by

$$a_{\text{max}} = 0.85k_1c_b$$

where $k_1$ is calculated as follows:

$$k_1 = 0.85 - 0.006 \left( f_{ck} - 25 \right), \quad 0.70 \leq k_1 \leq 0.85.$$  

(TS 7.11, 7.3, Eqn. 7.4)

If $a \leq a_{\text{max}}$, the area of tension reinforcement is then given by:

$$A_s = \frac{M_d}{f_{yd} \left( d - \frac{a}{2} \right)}$$

This reinforcement is to be placed at the bottom if $M_d$ is positive, or at the top if $M_d$ is negative.

Figure 17-1 Uniform Thickness Slab Design

- If $a \leq a_{\text{max}}$, the area of tension reinforcement is then given by:

$$A_s = \frac{M_d}{f_{yd} \left( d - \frac{a}{2} \right)}$$

This reinforcement is to be placed at the bottom if $M_d$ is positive, or at the top if $M_d$ is negative.
If $a > a_{\text{max}}$, compression reinforcement is required (TS 7.1) and is calculated as follows:

- The compressive force developed in the concrete alone is given by:
  \[
  C = 0.85 f_{cd} b a_{\text{max}},
  \]
  (TS 7.1)
  and the moment resisted by concrete compression and tension reinforcement is:
  \[
  M_{dc} = C \left( d - \frac{a_{\text{max}}}{2} \right).
  \]

- Therefore the moment required to be resisted by compression reinforcement and tension reinforcement is:
  \[
  M_{ds} = M_d - M_{dc}.
  \]

- The required compression reinforcement is given by:
  \[
  A'_s = \frac{M_{ds}}{\left( \sigma_s - 0.85 f_{cd} \right) \left( d - d' \right)},
  \]
  where
  \[
  \sigma_s = E_s \varepsilon_{cu} \left[ \frac{e_{\text{max}} - d'}{e_{\text{max}}} \right] \leq f_{yd}.
  \]
  (TS 7.1)

- The required tension reinforcement for balancing the compression in the concrete is:
  \[
  A_{11} = \frac{M_{ds}}{f_{yd} \left[ d - \frac{a_{\text{max}}}{2} \right]},
  \]
  and the tension reinforcement for balancing the compression reinforcement is given by:
  \[
  A_{12} = \frac{M_{ds}}{f_{yd} \left( d - d' \right)}.
  \]
Therefore, the total tension reinforcement is \( A_s = A_{s1} + A_{s2} \), and the total compression reinforcement is \( A' \). \( A_s \) is to be placed at the bottom and \( A' \) is to be placed at the top if \( M_d \) is positive, and vice versa if \( M_d \) is negative.

### 17.5.1.2.2 Design of nonuniform thickness slab

In designing a flanged-shaped section, a simplified stress block, as shown in Figure 17-2, is assumed if the flange is under compression, i.e., if the moment is positive. If the moment is negative, the flange comes under tension, and the flange is ignored. In that case, a simplified stress block similar to that shown in Figure 17-1 is assumed on the compression side.

**Figure 17-2 Nonuniform Thickness Slab Design**

#### 17.5.1.2.2.1 Flanged Slab Section Under Negative Moment

In designing for a factored negative moment, \( M_d \) (i.e., designing top reinforcement), the calculation of the reinforcement area is exactly the same as described previously, i.e., no flanged data is used.

#### 17.5.1.2.2.2 Flanged Slab Section Under Positive Moment

If \( M_d > 0 \), the depth of the compression block is given by:
Chapter 17 - Design for TS 500-2000

\[ a = d - \sqrt{d^2 - \frac{2M_d}{0.85 f_{cd} b_f}} \]

The maximum depth of the compression zone, \( c_b \), is calculated based on the compressive strength of the concrete and the tensile steel tension using the following equation (TS 7.1):

\[ c_b = \frac{e_s E_s}{e_{cu} E_s + f_{yd}} \]

(TS 7.1)

The maximum allowable depth of the rectangular compression block, \( a_{\text{max}} \), is given by

\[ a_{\text{max}} = 0.85 k_1 c_b \]

(TS 7.11, 7.3, Eqn. 7.4)

where \( k_1 \) is calculated as follows:

\[ k_1 = 0.85 - 0.006(f_{ck} - 25), \quad 0.70 \leq k_1 \leq 0.85. \]  

(TS 7.1, Table 7.1)

- If \( a \leq d_s \), the subsequent calculations for \( A_s \) are exactly the same as previously defined for the uniform thickness slab section design. However, in that case, the width of the slab is taken as \( b_f \), as shown in Figure 17-2. Compression reinforcement is required if \( a > a_{\text{max}} \).

- If \( a > d_s \), the calculation for \( A_s \) has two parts. The first part is for balancing the compressive force from the flange, \( C_f \), and the second part is for balancing the compressive force from the web, \( C_w \), as shown in Figure 17-2. \( C_f \) is given by:

\[ C_f = 0.85 f_{cd} (b_f - b_w) \times \min(d_s, a_{\text{max}}) \]

(TS 7.1)

Therefore, \( A_{n1} = \frac{C_f}{f_{yd}} \) and the portion of \( M_d \) that is resisted by the flange is given by:

\[ M_{df} = C_f \left( d - \frac{\min(d_s, a_{\text{max}})}{2} \right) \]
Therefore, the balance of the moment, $M_d$, to be carried by the web is given by:

$$M_{dw} = M_d - M_{df}$$

The web is a rectangular section of dimensions $b_w$ and $d$, for which the design depth of the compression block is recalculated as:

$$a_1 = d - \sqrt{d^2 - \frac{2M_{dw}}{0.85f_{cd}b_w}}$$  \hspace{1cm} \text{(TS 7.1)}$$

- If $a_1 \leq a_{max}$ (TS 7.1), the area of tensile steel reinforcement is then given by:

$$A_{s2} = \frac{M_{dw}}{f_{yd}(d - \frac{a_1}{2})}, \text{ and}$$

$$A_s = A_{s1} + A_{s2}$$

This steel is to be placed at the bottom of the T-shaped section.

- If $a_1 > a_{max}$, compression reinforcement is required and is calculated as follows:

The compression force in the web concrete alone is given by:

$$C = 0.85f_{cd}b_na_{max}$$ \hspace{1cm} \text{(TS 7.1)}$$

Therefore the moment resisted by the concrete:

$$M_{dc} = C\left(d - \frac{a_{max}}{2}\right),$$

The tensile steel for balancing compression in the web concrete is:

$$A_{s2} = \frac{M_{dc}}{f_{yd}\left[d - \frac{a_{max}}{2}\right]}$$

The moment resisted by compression steel and tensile steel is:
\[ M_{ds} = M_{dsw} - M_{dc} \]

Therefore, the compression steel is computed as:

\[ A_s' = \frac{M_{ds}}{(\sigma_s' - 0.85 f_{cd}) (d - d'')} \], where

\[ \sigma_s' = E_s e_{cu} \left[ \frac{e_{\max} - d'}{e_{\max}} \right] \leq f_{yd} \], and  \[ \text{(TS 7.1)} \]

the tensile steel for balancing the compression steel is:

\[ A_{x3} = \frac{M_{ds}}{f_{yd} (d - d'')} \]

The total tensile reinforcement is \( A_s = A_{x1} + A_{x2} + A_{x3} \), and the total compression reinforcement is \( A_s' \). \( A_s \) is to be placed at the bottom and \( A_s' \) is to be placed at the top.

### 17.5.1.2.3 Minimum and Maximum Tensile Reinforcement

The minimum flexural tension reinforcement required for each direction of a slab is given by the following limits (TS 11.4.5):

\[ A_{s, min} = 0.0020 \, bh \text{ for steel grade S220} \]  \[ \text{(TS 11.4.5)} \]

\[ A_{s, min} = 0.00175 \, bh \text{ for steel grade S420 and S500} \]  \[ \text{(TS 11.4.5)} \]

In addition, an upper limit on both the tension reinforcement and compression reinforcement has been imposed to be 0.04 times the gross cross-sectional area.

### 17.5.2 Design Slab Shear Reinforcement

The shear reinforcement is designed for each load combination at each station along the design strip. In designing the shear reinforcement for a particular strip, for a particular load combination, at a particular station due to the slab major shear, the following steps are involved:
- Determine the factored shear force, $V_d$.
- Determine the shear force, $V_c$, that can be resisted by the concrete.
- Determine the shear reinforcement required to carry the balance.

The following three sections describe in detail the algorithms associated with these steps.

### 17.5.2.1 Determine Factored Shear Force
In the design of the slab shear reinforcement, the shear forces for each load combination at a particular design strip station are obtained by factoring the corresponding shear forces for different load cases, with the corresponding load combination factors.

### 17.5.2.2 Determine Concrete Shear Capacity
Given the design force set $N_d$ and $V_d$, the shear force carried by the concrete, $V_c$, is calculated as follows:

- If the slab is subjected to axial loading, $N_d$ is positive in this equation regardless of whether it is a compressive or tensile force,

$$ V_{cr} = 0.65 f_{cd} b_a d \left( 1 + \frac{\gamma N_d}{A_g} \right), $$  

where,

- $0.07$ for axial compression
- $\gamma = -0.3$ for axial tension
- $0$ when tensile stress $< 0.5$ MPa

$$ V_c = 0.8 V_{cr}, $$  

### 17.5.2.3 Determine Required Shear Reinforcement
Given $V_d$ and $V_c$, the required shear reinforcement in the form of stirrups or ties within a spacing, $s$, is given for rectangular and circular columns by the following:
The shear force is limited to a maximum of

\[ V_{\text{max}} = 0.22 f_{cd} A_w \]  \hspace{1cm} (TS 8.1.5b)

The required shear reinforcement per unit spacing, \( A_v/s \), is calculated as follows:

If \( V_d \leq V_{cr} \),

\[ \frac{A_{sw}}{s} = 0.3 \frac{f_{cd}}{f_{ywd}} b_w, \]  \hspace{1cm} (TS 8.1.5, Eqn. 8.6)

else if \( V_{cr} < V_d \leq V_{\text{max}} \),

\[ \frac{A_{sw}}{s} = \frac{(V_d - V_{cr})}{f_{ywd}d} \]  \hspace{1cm} (TS 8.1.4, Eqn. 8.5)

\[ \frac{A_{sw}}{s} \geq 0.3 \frac{f_{cd}}{f_{ywd}} b_w \]  \hspace{1cm} (TS 8.1.5, Eqn. 8.6)

else if \( V_d > V_{\text{max}} \),

a failure condition is declared.  \hspace{1cm} (TS 8.1.5b)

If \( V_d \) exceeds its maximum permitted value \( V_{\text{max}} \), the concrete section size should be increased (TS 8.1.5b).

The maximum of all of the calculated \( A_{sw}/s \) values, obtained from each design load combination, is reported along with the controlling shear force and associated design load combination name.

The slab shear reinforcement requirements considered by the program are based purely on shear strength considerations. Any minimum stirrup requirements to satisfy spacing and volumetric considerations must be investigated independently of the program by the user.
17.5.3 Check for Punching Shear

The algorithm for checking punching shear is detailed in the section entitled “Slab Punching Shear Check” in the Chapter 1. Only the code-specific items are described in the following sections.

17.5.3.1 Critical Section for Punching Shear

The punching shear is checked on a critical section at a distance of $d/2$ from the face of the support (TS 8.3.1). For rectangular columns and concentrated loads, the critical area is taken as a rectangular area with the sides parallel to the sides of the columns or the point loads (TS 8.3.1). Figure 17-3 shows the auto punching perimeters considered by ETABS for the various column shapes. The column location (i.e., interior, edge, corner) and the punching perimeter may be overwritten using the Punching Check Overwrites.

![Figure 17-3 Punching Shear Perimeters](image-url)

- Interior Column
- Edge Column
- Edge Column
- Circular Column
- T-Shape Column
- L-Shape Column
17.5.3.2 Determine Concrete Capacity

The concrete punching shear stress capacity is taken as the following limit:

\[ v_{pc} = f_{cd} = 0.35 \sqrt{f_{ck}/\gamma_c} \]  

(TS 8.3.1)

17.5.3.3 Computation of Maximum Shear Stress

Given the punching shear force and the fractions of moments transferred by eccentricity of shear, the nominal design shear stress, \( v_{pd} \), is calculated as:

\[ v_{pd} = \frac{V_{pd}}{u_p d} \left[ 1 + \eta \left( \frac{0.4M_{pd,2}u_p d}{V_{pd} W_{m,2}} + \eta \frac{0.4M_{pd,3}u_p d}{V_{pd} W_{m,3}} \right) \right], \text{ where} \]  

(TS 8.3.1)

\[ \eta \] factor to be used in punching shear check

\[ \eta = \frac{1}{1 + \sqrt{b_2/b_1}} \text{ where } b_2 \geq 0.7b_1 \]

When the aspect ratio of loaded area is greater than 3, the critical perimeter is limited assuming \( h = 3b \)

\( u_p \) is the effective perimeter of the critical section

\( d \) is the mean effective depth of the slab

\( M_{pd} \) is the design moment transmitted from the slab to the column at the connection along bending axis 2 and 3

\( V_{pd} \) is the total punching shear force

\( W_m \) section modulus of area within critical punching perimeter \( (u_p) \) along bending axis 2 and 3.

17.5.3.4 Determine Capacity Ratio

Given the punching shear force and the fractions of moments transferred by eccentricity of shear about the two axes, the shear stress is computed assuming linear variation along the perimeter of the critical section. The ratio of the maximum shear stress and the concrete punching shear stress capacity is reported as
the punching shear capacity ratio by ETABS. If this ratio exceeds 1.0, punching shear reinforcement is designed as described in the following section.

17.5.4 Design Punching Shear Reinforcement

The use of shear studs as shear reinforcement in slabs is permitted, provided that the slab thickness is greater than or equal to 250 mm, a (TS 8.3.2). If the slab thickness does not meet these requirements, the punching shear reinforcement is not designed and the slab thickness should be increased by the user.

The algorithm for designing the required punching shear reinforcement is used when the punching shear capacity ratio exceeds unity. The Critical Section for Punching Shear and Transfer of Unbalanced Moment as described in the earlier sections remain unchanged. The design of punching shear reinforcement is described in the subsections that follow.

17.5.4.1 Determine Concrete Shear Capacity

The concrete punching shear stress capacity of a section with punching shear reinforcement is limited to:

\[ v_{pr} = f_{cd} = 0.35 \sqrt{f_{ck}} / \gamma_c \]

(TS 8.3.1)

17.5.4.2 Determine Required Shear Reinforcement

The shear force is limited to a maximum of:

\[ v_{pr,\text{max}} = 1.5 \gamma f_{cd} = 0.525 \gamma \sqrt{f_{ck}} / \gamma_c \text{ for shear links/shear studs} \]

(TS 8.3.1)

Given \( V_{pd} \), \( V_{pr} \), and \( V_{pr,\text{max}} \), the required shear reinforcement is calculated as follows,

\[ A_s = \left( \frac{V_{pd} - V_{pr}}{f_{yd} d} \right) \]

(TS 8.1.4 )

- If \( V_{pd} > V_{pr,\text{max}} \), a failure condition is declared. (TS 8.3.1)
- If \( V_{pd} \) exceeds the maximum permitted value of \( V_{pr,\text{max}} \), the concrete section should be increased in size.
### 17.5.4.3 Determine Reinforcement Arrangement

Punching shear reinforcement in the vicinity of rectangular columns should be arranged on peripheral lines, i.e., lines running parallel to and at constant distances from the sides of the column. Figure 17-4 shows a typical arrangement of shear reinforcement in the vicinity of a rectangular interior, edge, and corner column.

**NOTE:** Shear Stud and shear links requirements are computed based on ACI 318-08 code as Turkish TS 500-2000 refers to special literature on this topic.

![Typical Studrail](image)

**Figure 17-4 Typical arrangement of shear studs and critical sections outside shear-reinforced zone**

The distance between the column face and the first line of shear reinforcement shall not exceed \(d/2\) (ACI R11.3.3, 11.11.5.2). The spacing between adjacent shear reinforcement in the first line (perimeter) of shear reinforcement shall not exceed \(2d\) measured in a direction parallel to the column face (ACI 11.11.3.3).

Punching shear reinforcement is most effective near column corners where there are concentrations of shear stress. Therefore, the minimum number of lines of shear reinforcement is 4, 6, and 8, for corner, edge, and interior columns respectively.
17.5.4.4 Determine Reinforcement Diameter, Height, and Spacing

The punching shear reinforcement is most effective when the anchorage is close to the top and bottom surfaces of the slab. The cover of anchors should not be less than the minimum cover specified in ACI 7.7 plus half of the diameter of the flexural reinforcement.

Punching shear reinforcement in the form of shear studs is generally available in 10-, 12-, 14-, 16-, and 20-millimeter diameters.

When specifying shear studs, the distance, $s_o$, between the column face and the first peripheral line of shear studs should not be smaller than $0.5d$. The spacing between adjacent shear studs, $g$, at the first peripheral line of studs shall not exceed $2d$, and in the case of studs in a radial pattern, the angle between adjacent stud rails shall not exceed 60 degrees. The limits of $s_o$ and the spacing, $s$, between the peripheral lines are specified as:

$$s_o \leq 0.5d$$  \hspace{1cm} \text{(ACI 11.11.5.2)}

$$s \leq\begin{cases} 
0.75d & \text{for } \nu_u \leq 6\phi\lambda\sqrt{f'_c} \\
0.50d & \text{for } \nu_u > 6\phi\lambda\sqrt{f'_c}
\end{cases}$$  \hspace{1cm} \text{(ACI 11.11.5.2)}

$$g \leq 2d$$  \hspace{1cm} \text{(ACI 11.11.5.3)}

The limits of $s_o$ and the spacing, $s$, between for the links are specified as:

$$s_o \leq 0.5d$$  \hspace{1cm} \text{(ACI 11.11.3)}

$$s \leq 0.50d$$  \hspace{1cm} \text{(ACI 11.11.3)}
